Revision 1.2.5

### 1.1.2 Change History

Issue	Date	By	Change
Revision 1.0	29.10.04	C. Horst	First complete revision
Revision 1.0.1	16.11.04	C. Horst	Message Buffer Status bits PLE, MLST, ES replaced by bits ESA, ESB, MLST
Revision 1.0.2	28.01.05	C. Horst	IBCR, IBCM, OBCR, OBCM: addresses changed MHDC2: register removed MHDC1: renamed to MHDC Message buffer 0 dedicated to hold key slot ID SFS: description updated ESIDn, OSIDn: description updated EIR: bit SCE removed EILS: bit SCEL removed EIES, EIER: bit SCEE removed
Revision 1.1 working	29.04.05	C. Horst	State DEFAULT_CONFIG added to POC CCSV: assignment of states to POCS[5:0] changed: POCS[5:0] = 00 0000 = DEFAULT_CONFIG POCS[5:0] = 00 1111 = CONFIG CCSV: bit DCREQ removed SIR: bit MBSI added SILS: bit MBSIL added SIES, SIER: bit MBSIE added Register BGSC removed EIR: bits SMEB, SMEA removed EILS: bits SMEBL, SMEAL removed EIES, EIER: bits SMEBE, SMEAE removed Registers TXRQ3, TXRQ4, NDAT3, NDAT4, MBSC3, MBSC4 added Bus guardian related pins <b>eray_arm</b> , <b>eray_bgt</b> , <b>eray_mt</b> , <b>eray_bge1</b> , and <b>eray_bge2</b> have no function PRTC1: Configuration parameter CASM[6:0] added WRHS1: Bit NME changed to PPIT RDHS1: Bit NME changed to PPIT Pin <b>eray_scanmode</b> for scan mode control added
Revision 1.1	04.08.05	C. Horst	EIR: Flags CCL, EFA, IIBA, IOBA, TABA, TABB added SIR: Flag SDS added EILS: Control bits CCLL, EFAL, IIBAL, IOBAL, TABAL, TABBL added SILS: Control bit SDSL added

manual\_about.fm

			EIES: Control bits CCLE, EFAE, IIBAE, IOBAE, TABAE, TABBE added EIER: Control bits CCLE, EFAE, IIBAE, IOBAE, TABAE, TABBE added SIES: Control bit SDSE added SUCC2: LT[20:0] range modified PRTC1: TSST[3:0] range modified PRTC1: TSST[3:0] range modified MHDC: SLT[12:0] range modified GTUC1: UT[19:0] range modified GTUC1: UT[19:0] range modified GTUC2: MPC[13:0] range modified GTUC3: Configuration parameter MTIO[5:0] replaced by MIOA[6:0] and MIOB[6:0] GTUC4: NIT[13:0] range modified GTUC7: SSL[9:0] range modified GTUC7: SSL[9:0] range modified GTUC7: SSL[9:0] range modified GTUC8: NMS[12:0] range modified GTUC9: APO[5:0] and DSI[1:0] range modified GTUC10: MOC[13:0] range modified GTUC11: Configuration parameter ECC[1:0] replaced by EOCC[1:0] and ERCC[1:0] OCV: OCV[18:0] range modified SCV: SCCA[10:0], SCCB[10:0] range modified ACS: Flags can only be reset MRC: Configuration bits SEC[1:0] added Register LDTS added Bus guardian related pins <b>eray_arm, eray_bgt,</b> <b>eray_mt, eray_bge1,</b> and <b>eray_bge2</b> removed from physical layer interface Chapter 6. Restrictions removed. Description of timing requirements for data transfers between Message RAM and IBF / OBF moved to "Addendum to E-Ray FlexRay IP-Module Specification Revision 1.1"
Revision 1.2	09.12.05	C. Horst	Section 3.2 renamed from "Interrupt Flag Interface" to "Internal Signal and Flag Interface" With this revision it is possible to use message buffer 1 for sync frame transmission in addition to message buffer 0 if sync frames should have different payloads on channel A and B EIR: Handling of bits PERR and RFO same as for other bits, bit MHF added SIR: Bit RFF renamed to RFCL, handling of bits RFNE, RFCL same as for other bits EILS: Bit MHFL added SILS: Bit RFFL renamed to RFCLL EIES, EIER: Bit MHFE added SIES, SIER: Bit RFFE renamed to RFCLE

			Register STPW renamed to STPW1
			STPW2: Register added
			CCSV: Bits PSL[5:0] added SWNIT: Bits MTSA, MTSB added
			MRC: Bit SPLM added
			FCL: Register added
			FSR: Register added
			MHDF: Register added
			MBSC1/2/3/4: Naming of bits changed from MBS to
			MBC to distinguish between message buffer status flag
			(MBC) and message buffer status register (MBS)
			CREL: Register added
			ENDN: Register added
			Message buffers in Message RAM:
			Header 2 and 3 updated from received data frames only
			MBS: Bits FTA, FTB, CCS[5:0], RCIS, SFIS, SYNS,
			NFIS, PPIS, RESS added

# **1.2 Conventions**

E-Ray

The following conventions are used within this document:

Times bold	Names of bits and signals
CAPITALS	POC states and CHI commands

## **1.3 Definitions**

FlexRay Frame:	Header Segment + Payload Segment
Message Buffer:	Header Section + Data Section
Message RAM:	Header Partition + Data Partition
Data Frame:	FlexRay frame that is not a null frame

# 1.4 Scope

This document describes the E-Ray FlexRay IP-module and its features from the application programmer's point of view. All information necessary to integrate the E-Ray module into an user-defined ASIC is located in the Module Integration Guide. Information about a specific Customer CPU Interface can be found in the respective Customer CPU Interface Specification document.

# 1.5 References

# **1.6 Terms and Abbreviations**

This document uses the following terms and abbreviations:

Term	Meaning
AP	Action Point
BD	Bus Driver
BSS	Byte Start Sequence
CAS	Collision Avoidance Symbol
CC	Communication Controller
CHI	Controller Host Interface
CIF	Customer Interface Block
CRC	Cyclic Redundancy Check
FES	Frame End Sequence
FSS	Frame Start Sequence
FIFO	First In First Out (message buffer structure)
FSM	Finite State Machine
FSP	Frame and Symbol Processing Block
FTM	Fault Tolerant Midpoint
GIF	Generic Interface Block
GTU	Global Time Unit Block
IBF	Input Buffer
INT	Interrupt Control Block
MHD	Message Handler Block
MT	Macrotick
MTS	Media Access Test Symbol
NCT	Network Communication Time
NEM	Network Management Block
NIT	Network Idle Time
NM	Network Management
OBF	Output Buffer
POC	Protocol Operation Control
PRT	Protocol Controller Block
SDL	Specification and Description Language
SUC	System Universal Control Block
TBF	Transient Buffer
TDMA	Time Division Multiple Access (media access method)

**BOSCH** 

TSS	Transmission Start Sequence
TT-D	Time Triggered Distributed Synchronization
μΤ	Microtick
WUP	Wakeup Pattern
WUS	Wakeup Symbol

# 2. Overview

The E-Ray module is a FlexRay IP-module that can be integrated as stand-alone device or as part of an ASIC. It is described in VHDL on RTL level, prepared for synthesis. The E-Ray IP-module performs communication according to the FlexRay protocol specification v2.1. With maximum specified sample clock the bitrate is 10 MBit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

For communication on a FlexRay network, individual message buffers with up to 254 data bytes are configurable. The message storage consists of a single-ported Message RAM that holds up to 128 message buffers. All functions concerning the handling of messages are implemented in the Message Handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay Channel Protocol Controllers and the Message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the E-Ray IP-module can be accessed directly by an external Host via the module's Host interface. These registers are used to control/configure/monitor the FlexRay Channel Protocol Controllers, Message Handler, Global Time Unit, System Universal Control, Frame and Symbol Processing, Network Management, Interrupt Control, and to access the Message RAM via Input / Output Buffer.

The E-Ray IP-module can be connected to a wide range of customer-specific Host CPUs via its 8/16/32-bit Generic CPU Interface.

#### The E-Ray IP-module supports the following features:

- Conformance with FlexRay protocol specification v2.1
- Data rates of up to 10 Mbit/s on each channel
- Up to 128 message buffers configurable
- 8 Kbyte of Message RAM for storage of e.g. 128 message buffers with max. 48 byte data section or up to 30 message buffers with 254 byte data section
- Configuration of message buffers with different payload lengths possible
- One configurable receive FIFO
- Each message buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO
- Host access to message buffers via Input and Output Buffer Input Buffer: Holds message to be transferred to the Message RAM
   Output Buffer: Holds message read from the Message RAM
- Filtering for slot counter, cycle counter, and channel
- Maskable module interrupts
- Network Management supported
- 8/16/32-bit Generic CPU Interface, connectable to a wide range of customer-specific Host CPUs

# 2.1 Block Diagram

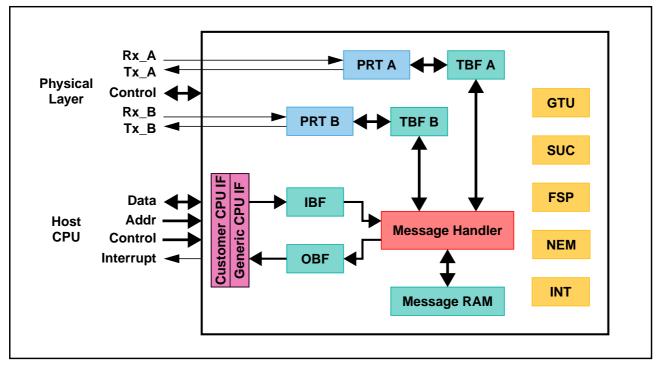

Figure 1: E-Ray block diagram

#### Customer CPU Interface (CIF)

Connects a customer specific Host CPU to the E-Ray IP-module via the Generic CPU Interface.

#### Generic CPU Interface (GIF)

The E-Ray IP-module is provided with an 8/16/32-bit Generic CPU Interface prepared for the connection to a wide range of customer-specific Host CPUs. Configuration registers, status registers, and interrupt registers are attached to the respective blocks and can be accessed via the Generic CPU Interface.

#### **Input Buffer (IBF)**

For write access to the message buffers configured in the Message RAM, the Host can write the header and data section for a specific message buffer to the Input Buffer. The Message Handler then transfers the data from the Input Buffer to the selected message buffer in the Message RAM.

#### **Output Buffer (OBF)**

For read access to a message buffer configured in the Message RAM the Message Handler transfers the selected message buffer to the Output Buffer. After the transfer has completed, the Host can read the header and data section of the transferred message buffer from the Output Buffer.

#### Message Handler (MHD)

The E-Ray Message Handler controls data transfers between the following components:

- Input / Output Buffer and Message RAM
- Transient Buffer RAMs of the two FlexRay Protocol Controllers and Message RAM

#### Message RAM (MRAM)

The Message RAM consists of a single-ported RAM that stores up to 128 FlexRay message buffers together with the related configuration data (header and data partition).

#### Transient Buffer RAM (TBF A/B)

Stores the data section of two complete messages.

#### FlexRay Channel Protocol Controller (PRT A/B)

The FlexRay Channel Protocol Controllers consist of shift register and FlexRay protocol FSM. They are connected to the Transient Buffer RAMs for intermediate message storage and to the physical layer via bus driver BD.

They perform the following functionality:

- Control and check of bit timing
- Reception / transmission of FlexRay frames and symbols
- Check of header CRC
- Generation / check of frame CRC
- Interfacing to bus driver

The FlexRay Channel Protocol Controllers have interfaces to:

- Physical Layer (bus driver)
- Transient Buffer RAM
- Message Handler
- Global Time Unit
- System Universal Control
- Frame and Symbol Processing
- Network Management
- Interrupt Control

#### **Global Time Unit (GTU)**

The Global Time Unit performs the following functions:

- Generation of microtick
- Generation of macrotick
- Fault tolerant clock synchronization by FTM algorithm
  - rate correction
  - offset correction
- Cycle counter

nanual\_overview.fm

- Timing control of static segment
- Timing control of dynamic segment (minislotting)
- Support of external clock correction

#### System Universal Control (SUC)

The System Universal Control controls the following functions:

- Configuration
- Wakeup
- Startup
- Normal Operation
- Passive Operation
- Monitor Mode

#### Frame and Symbol Processing (FSP)

The Frame and Symbol Processing controls the following functions:

- Checks the correct timing of frames and symbols
- Tests the syntactical and semantical correctness of received frames
- Sets the slot status flags

#### Network Management (NEM)

Handles the network management vector.

#### Interrupt Control (INT)

The Interrupt Controller performs the following functions:

- Provides error and status interrupt flags
- Enable / disable interrupt sources
- Assignment of interrupt sources to one of the two module interrupt lines
- Enable / disable module interrupt lines
- Manages the two interrupt timers
- Stop watch time capturing

# **3. Generic Interface**

The Generic Interface encapsulates the synthesizable code of the E-Ray design (E-Ray core). All customer specific components like Customer CPU Interfaces and RAM blocks are connected to the Generic Interface.

The Generic CPU Interface connects the E-Ray module to a customer specific Host CPU via the Customer CPU Interface. It supports 8/16/32-bit access modes.

# 4. Programmer's Model

# 4.1 Register Map

E-Ray

The E-Ray module allocates an address space of 2 Kbytes (0x0000 to 0x07FF). The registers are organized as 32-bit registers. 8/16-bit accesses are also supported. Host access to the Message RAM is done via the Input and Output Buffers. They buffer data to be transferred to and from the Message RAM under control of the Message Handler, avoiding conflicts between Host accesses and message reception / transmission. Addresses 0x0000 to 0x000F are reserved for customer specific purposes. All functions related to these addresses are located in the Customer CPU Interface.

The assignment of the message buffers is done according to the scheme shown in Table 1 below. The number N of available message buffers depends on the payload length of the configured message buffers. The maximum number of message buffers is 128. The maximum payload length supported is 254 bytes.

The message buffers are separated into three consecutive groups:

- Static Buffers Transmit / receive buffers assigned to static segment
- Static + Dynamic Buffers Transmit / receive buffers assigned to static or dynamic segment
- FIFO Receive FIFO

The message buffer separation configuration can be changed only in DEFAULT\_CONFIG or CON-FIG state only by programming register MRC (see 4.7.1 Message RAM Configuration (MRC)).

The first group starts with message buffer 0 and consists of static message buffers only. Message buffer 0 is dedicated to hold the startup / sync frame or the single slot frame, if the node transmits one, as configured by **SUCC1.TXST**, **SUCC1.TXSY**, and **SUCC1.TSM**. In addition, message buffer 1 may be used for sync frame transmission in case that sync frames or single-slot frames should have different payloads on the two channels. In this case bit **MRC.SPLM** has to be programmed to '1' and message buffers 0 and 1 have to be configured with the key slot ID and can be (re)configured in DEFAULT\_CONFIG or CONFIG state only.

The second group consists of message buffers assigned to the static or to the dynamic segment. Message buffers belonging to this group may be reconfigured during run time from dynamic to static or vice versa depending on the state of **MRC.SEC[1:0]**.

manual\_programmers\_model.fm

The message buffers belonging to the third group are concatenated to a single receive FIFO.

Message Buffer 0	↓ Static Buffers	
Message Buffer 1		
	↓ Static + Dynamic Buffers	⇐ FDB
	↓ FIFO	⇐ FFB
Message Buffer N-1		
Message Buffer N		⇐ LCB

Table 1: Assignment of message buffers

Table 2: E-Ray register map

# 4.2 Customer Registers

The address space from 0x0000 to 0x000F is reserved for customer-specific registers. These registers, if implemented, are located in the Customer CPU Interface block. A description can be found in the specific Customer CPU Interface specification document.

# 4.3 Special Registers

#### 4.3.1 Lock Register (LCK)

The Lock Register is write-only. Reading the register will return 0x0000 0000.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LCK	R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
0x001C	W																
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	W									CLK7	CLK6	CLK5	CLK4	CLK3	CLK2	CLK1	CLK0
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CLK[7:0] Configuration Lock Key

To leave CONFIG state by writing **SUCC1.CMD[3:0]** (commands READY, MONITOR\_MODE, ATM, LOOP\_BACK), the write operation has to be directly preceded by two write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the SUCC1 register, the CC remains in CONFIG state and the sequence has to be repeated.

First write:	LCK.CLK[7:0]	= "1100 1110" (0xCE)
Second write:	LCK.CLK[7:0]	= "0011 0001" (0x31)
Third write:	SUCC1.CMD[3:0]	

**Note:** In case that the Host uses 8/16-bit accesses to write **CLK[7:0**], the programmer has to ensure that no "dummy accesses" e.g. to the remaining register bytes / words are inserted by the compiler.

# 4.4 Interrupt Registers

#### 4.4.1 Error Interrupt Register (EIR)

The flags are set when the CC detects one of the listed error conditions. The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect on the flag. A hard reset will also clear the register.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EIR	R	0	0	0	0	0	TADD	ITVD	EDB	0	0	0	0	0	тара	I TUA	EDA
0x0020	W						TABB	LTVB	ЕДР						TABA	LTVA	EDA
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	R	0	0	0	0	MHF	IODA	IIBA	EFA	RFO	PERR	CCI	CCE	SFO	SEDM	CNA	DEMC
	W					МПГ	IOBA	IIDA	ЕГА	кго	PEKK	CCL	CCF	310	SFBM	CNA	PEMC
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### **PEMC** POC Error Mode Changed

This flag is set whenever the error mode signalled by CCEV.ERRM[1:0] has changed.

- 1 = Error mode has changed
- 0 = Error mode has not changed

#### CNA Command Not Accepted

The flag signals that the write access to the CHI command vector **SUCC1.CMD[3:0]** was not successful because the requested command was not valid in the actual POC state, or because the CHI command was locked (**CCL** = '1').

- 1 = CHI command not accepted
- 0 = CHI command accepted

#### SFBM Sync Frames Below Minimum

This flag signals that the number of sync frames received during the last communication cycle was below the limit required by the FlexRay protocol. May be set during startup and therefore should be cleared by the Host after the CC entered NORMAL\_ACTIVE state.

- 1 = Less than the required minimum of sync frames received
- 0 = Sync node: 1 or more sync frames received, non-sync node: 2 or more sync frames received

#### SFO Sync Frame Overflow

Set when either the number of sync frames received during the last communication cycle or the total number of sync frames received during the last double cycle exceeds the maximum number of sync frames as defined by **GTUC2.SNM[3:0]**.

1 = More sync frames received than configured by **GTUC2.SNM[3:0]** 

0 = Number of received sync frames  $\leq$  **GTUC2.SNM[3:0]** 

#### CCF Clock Correction Failure

This flag is set at the end of the cycle whenever one of the following errors occurred:

- Missing offset and / or rate correction
- Clock correction limit reached

The clock correction status is monitored in registers CCEV and SFS. A failure may occur during startup, therefore bit **CCF** should be cleared by the Host after the CC entered NORMAL\_ACTIVE state.

- 1 = Clock correction failed
- 0 = No clock correction error

#### CCL CHI Command Locked

The flag signals that the write access to the CHI command vector **SUCC1.CMD[3:0]** was not successful because the execution of the previous CHI command has not yet completed. In this case bit **CNA** is also set to '1'.

- 1 = CHI command not accepted
- 0 = CHI command accepted

#### PERR Parity Error

The flag signals a parity error to the Host. It is set whenever one of the flags **MHDS.PIBF**, **MHDS.POBF**, **MHDS.POBF**, **MHDS.PTBF1**, **MHDS.PTBF2** changes from '0' to '1'.

- 1 = Parity error detected
- 0 = No parity error detected

#### **RFO** Receive FIFO Overrun

The flag is set by the CC when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. The actual state of the FIFO is monitored in register FSR.

1 = A receive FIFO overrun has been detected

0 = No receive FIFO overrun detected

#### **EFA** Empty FIFO Access

This flag is set by the CC when the Host requests the transfer of a message from the receive FIFO via Output Buffer while the receive FIFO is empty.

- 1 = Host access to empty FIFO occurred
- 0 = No Host access to empty FIFO occurred

#### IIBA Illegal Input Buffer Access

This flag is set by the CC when the Host wants to modify a message buffer via Input Buffer while the CC is not in CONFIG or DEFAULT\_CONFIG state and one of the following conditions applies:

- 1) The Host writes to the Input Buffer Command Request register to modify the
- Header section of message buffer 0, 1 if configured for transmission in key slot
- Header section of static message buffers with buffer number < MRC.FDB[7:0] while MRC.SEC[1:0] = "01"
- Header section of any static or dynamic message buffer while **MRC.SEC[1:0]** = "1x"
- Header and / or data section of any message buffer belonging to the receive FIFO
- 2) The Host writes to any register of the Input Buffer while IBCR.IBSYH is set to '1'.
- 1 = Illegal Host access to Input Buffer occurred
- 0 = No illegal Host access to Input Buffer occurred

#### **IOBA** Illegal Output buffer Access

This flag is set by the CC when the Host requests the transfer of a message buffer from the Message RAM to the Output Buffer while **OBCR.OBSYS** is set to '1'.

- 1 = Illegal Host access to Output Buffer occurred
- 0 = No illegal Host access to Output Buffer occurred

#### MHF Message Handler Constraints Flag

The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags MHDF.SNUA, MHDF.SNUB, MHDF.FNFA, MHDF.FNFB, MHDF.TBFA, MHDF.TBFB, MHDF.WAHP changes from '0' to '1'.

- 1 = Message Handler failure detected
- 0 = No Message Handler failure detected

Channel-specific error flags:

**EDA** Error Detected on Channel A

This bit is set whenever one of the flags ACS.SEDA, ACS.CEDA, ACS.CIA, ACS.SBVA changes from '0' to '1'.

- 1 = Error detected on channel A
- 0 = No error detected on channel A
- LTVA Latest Transmit Violation Channel A

The flag signals a latest transmit violation on channel A to the Host.

- 1 = Latest transmit violation detected on channel A
- 0 = No latest transmit violation detected on channel A

#### **TABA**Transmission Across Boundary Channel A

The flag signals to the Host that a transmission across a slot boundary occurred for channel A.

- 1 = Transmission across slot boundary detected on channel A
- 0 = No transmission across slot boundary detected on channel A
- **EDB** Error Detected on Channel B

This bit is set whenever one of the flags ACS.SEDB, ACS.CEDB, ACS.CIB, ACS.SBVB changes from '0' to '1'.

- 1 = Error detected on channel B
- 0 = No error detected on channel B

#### LTVB Latest Transmit Violation Channel B

The flag signals a latest transmit violation on channel B to the Host.

- 1 = Latest transmit violation detected on channel B
- 0 = No latest transmit violation detected on channel B

#### **TABB**Transmission Across Boundary Channel B

The flag signals to the Host that a transmission across a slot boundary occurred for channel B.

- 1 = Transmission across slot boundary detected on channel B
- 0 = No transmission across slot boundary detected on channel B

#### 4.4.2 Status Interrupt Register (SIR)

E-Ray

The flags are set when the CC detects one of the listed events. The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect on the flag. A hard reset will also clear the register.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SIR	R	0	0	0	0	0	0	MTCD	WIDD	0	0	0	0	0	0	MTGA	WIDA
0x0024	W							MTSB	WUPB							MTSA	WUPA
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	R W	SDS	MBSI	SUCS	SWE	TOBC	TIBC	TI1	TIO	NMVC	RFCL	RFNE	RXI	TXI	CYCS	CAS	WST
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### WST Wakeup Status

This flag is set when the wakeup status vector **CCSV.WSV[2:0]** is changed by a protocol event.

- 1 = Wakeup status changed
- 0 = Wakeup status unchanged

#### CAS Collision Avoidance Symbol

This flag is set by the CC during STARTUP state when a CAS or a potential CAS was received.

- 1 = Bit pattern matching the CAS symbol received
- 0 = No bit pattern matching the CAS symbol received

#### CYCS Cycle Start Interrupt

This flag is set by the CC when a communication cycle starts.

- 1 = Communication cycle started
- 0 = No communication cycle started

#### TXI Transmit Interrupt

This flag is set by the CC at the end of frame transmission if bit **MBI** in the respective message buffer is set to '1' (see Table 17).

- 1 = At least one frame was transmitted from a transmit buffer with **MBI** = '1'
- 0 = No frame transmitted from a transmit buffer with **MBI** = '1'

#### **RXI** Receive Interrupt

manual\_programmers\_model.fm

This flag is set by the CC whenever the set condition of a message buffers ND flag is fulfilled (see 4.8.6 New Data 1/2/3/4 (NDAT1/2/3/4)), and if bit **MBI** of that message buffer is set to '1' (see Table 17).

1 = At least one ND flag of a receive buffer with **MBI** = '1' has been set to '1'

0 = No ND flag of a receive buffer with **MBI** = '1' has been set to '1'

#### **RFNE** Receive FIFO Not Empty

This flag is set by the CC when a received valid frame was stored into the empty receive FIFO. The actual state of the receive FIFO is monitored in register FSR.

- 1 = Receive FIFO is not empty
- 0 = Receive FIFO is empty

#### **RFCL** Receive FIFO Critical Level

This flag is set when the receive FIFO fill level **FSR.RFFL**[7:0] is equal or greater than the critical level as configured by **FCL.CL**[7:0].

- 1 = Receive FIFO critical level reached
- 0 = Receive FIFO below critical level

- NMVC Network Management Vector Changed
  - This interrupt flag signals a change in the Network Management Vector visible to the Host.
  - 1 = Network management vector changed
  - 0 = No change in the network management vector

#### **TI0** Timer Interrupt 0

This flag is set whenever timer 0 matches the conditions configured in register T0C. A Timer Interrupt 0 is also signalled on pin **eray\_tint0**.

1 = Timer Interrupt 0 occurred

0 = No Timer Interrupt 0

#### TI1 Timer Interrupt 1

This flag is set whenever timer 1 matches the conditions configured in register T1C. A Timer Interrupt 1 is also signalled on pin **eray\_tint1**.

- 1 = Timer Interrupt 1 occurred
- 0 = No Timer Interrupt 1

#### **TIBC**Transfer Input Buffer Completed

This flag is set whenever a transfer from Input Buffer to the Message RAM has completed and **IBCR.IBSYS** has been reset by the Message Handler.

- 1 = Transfer between Input Buffer and Message RAM completed
- 0 = No transfer completed

#### **TOBC** Transfer Output Buffer Completed

This flag is set whenever a transfer from the Message RAM to the Output Buffer has completed and **OBCR.OBSYS** has been reset by the Message Handler.

- 1 = Transfer between Message RAM and Output Buffer completed
- 0 = No transfer completed

#### **SWE** Stop Watch Event

This flag is set after a stop watch activation when the actual cycle counter and macrotick value are stored in the Stop Watch register (see section 4.4.10 Stop Watch Register 1 (STPW1)).

- 1 = Stop Watch Event occurred
- 0 = No Stop Watch Event

#### SUCS Startup Completed Successfully

This flag is set whenever a startup completed successfully and the CC entered NORMAL\_ACTIVE state.

1 = Startup completed successfully

0 = No startup completed successfully

#### MBSI Message Buffer Status Interrupt

This flag is set by the CC when the message buffer status **MBS** has changed if bit **MBI** of that message buffer is set (see Table 17).

- 1 = Message buffer status of at least one message buffer with **MBI** = '1' has changed
- 0 = No message buffer status change of message buffer with **MBI** = '1'

#### SDS Start of Dynamic Segment

This flag is set by the CC when the dynamic segment starts.

- 1 = Dynamic segment started
- 0 = Dynamic segment not yet started

nanual\_programmers\_model.fm

Channel-specific status flags:

WUPA Wakeup Pattern Channel A

This flag is set by the CC when a wakeup pattern was received on channel A. Only set when the CC is in WAKEUP, READY, or STARTUP state, or when in Monitor mode.

- 1 = Wakeup pattern received on channel A
- 0 = No wakeup pattern received on channel A

#### MTSA MTS Received on Channel A (vSS!ValidMTSA)

Media Access Test symbol received on channel A during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

- 1 = MTS symbol received on channel A
- 0 = No MTS symbol received on channel A
- WUPB Wakeup Pattern Channel B

This flag is set by the CC when a wakeup pattern was received on channel B. Only set when the CC is in WAKEUP, READY, or STARTUP state, or when in Monitor mode.

- 1 = Wakeup pattern received on channel B
- 0 = No wakeup pattern received on channel B

#### MTSB MTS Received on Channel B (vSS!ValidMTSB)

Media Access Test symbol received on channel B during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

- 1 = MTS symbol received on channel B
- 0 = No MTS symbol received on channel B

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4.4.3 Error Interrupt Line Select (EILS)

The Error Interrupt Line Select register assigns an interrupt generated by a specific error interrupt flag from register EIR to one of the two module interrupt lines:

1 = Interrupt assigned to interrupt line **eray\_int1** 

0 = Interrupt assigned to interrupt line **eray\_int0** 

PEMCL	POC Error Mode Changed Interrupt Line

CNAL Command Not Accepted Interrupt Line

SFBML Sync Frames Below Minimum Interrupt Line

 Transmission Across Boundary Channel B Interrupt Line

# 4.4.4 Status Interrupt Line Select (SILS)

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SILS	R	0	0	0	0	0	0	MTSBL	WIIDDI	0	0	0	0	0	0	MTGAL	WUPAL
0x002C	W							MISDL	WUPBL							MISAL	WUPAL
Reset		0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1
Bit		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	R W	SDSL	MBSIL	SUCSL	SWEL	TOBCL	TIBCL	TI1L	TIOL	NMVCL	RFCLL	RFNEL	RXIL	TXIL	CYCSL	CASL	WSTL
Reset		1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The Status Interrupt Line Select register assign an interrupt generated by a specific status interrupt flag from register SIR to one of the two module interrupt lines:

1 = Interrupt assigned to interrupt line **eray\_int1** 

0 = Interrupt assigned to interrupt line **eray\_int0** 

#### 4.4.5 Error Interrupt Enable Set / Reset (EIES, EIER)

The settings in the Error Interrupt Enable register determine which status changes in the Error Interrupt Register will result in an interrupt.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EIES,R	R	0	0	0	0	0				0	0	0	0	0			
S:0x0030 R:0x0034	w						TABBE	LTVBE	EDBE						TABAE	LTVAE	EDAE
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	R	0	0	0	0	MHEE	IODAE	IIDAE	EFAE	DEOE	PERRE	CCLE	CCFE	SFOE	CEDME	CNAE	DEMCE
	W					MALE	IOBAE	IIBAE	EFAE	KFUE	PEKKE	ULLE	UCFE	SFUE	SFBME	UNAE	PEMCE
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The enable bits are set by writing to address 0x0030 and reset by writing to address 0x0034. Writing a '1' sets / resets the specific enable bit, writing a '0' has no effect. Reading from both addresses will result in the same value.

1 = Interrupt enabled

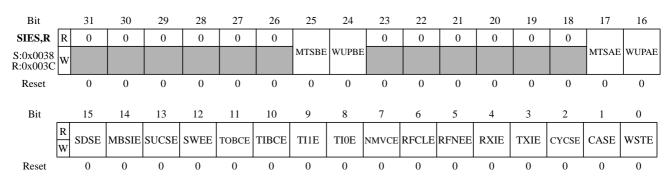

0 = Interrupt disabled

PEMCE	POC Error Mode Changed Interrupt Enable
CNAE	Command Not Accepted Interrupt Enable
SFBME	Sync Frames Below Minimum Interrupt Enable
SFOE	Sync Frame Overflow Interrupt Enable
CCFE	Clock Correction Failure Interrupt Enable
CCLE	CHI Command Locked Interrupt Enable
PERRE	Parity Error Interrupt Enable
RFOE	Receive FIFO Overrun Interrupt Enable
EFAE	Empty FIFO Access Interrupt Enable
IIBAE	Illegal Input Buffer Access Interrupt Enable
IOBAE	Illegal Output Buffer Access Interrupt Enable
MHFE	Message Handler Constraints Flag Interrupt Enable
EDAE	Error Detected on Channel A Interrupt Enable
LTVAE	Latest Transmit Violation Channel A Interrupt Enable
TABAE	Transmission Across Boundary Channel A Interrupt Enable
EDBE	Error Detected on Channel B Interrupt Enable
LTVBE	Latest Transmit Violation Channel B Interrupt Enable
TABBE	Transmission Across Boundary Channel B Interrupt Enable

**BOSCH** 

#### 4.4.6 Status Interrupt Enable Set / Reset (SIES, SIER)

The settings in the Status Interrupt Enable register determine which status changes in the Status Interrupt Register will result in an interrupt.

The enable bits are set by writing to address 0x0038 and reset by writing to address 0x003C. Writing a '1' sets / resets the specific enable bit, writing a '0' has no effect. Reading from both addresses will result in the same value.

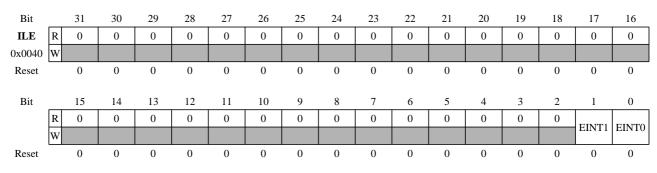

1 = Interrupt enabled

0 = Interrupt disabled

WSTE	Wakeup Status Interrupt Enable
CASE	Collision Avoidance Symbol Interrupt Enable
CYCSE	Cycle Start Interrupt Enable
TXIE	Transmit Interrupt Enable
RXIE	Receive Interrupt Enable
RFNEE	Receive FIFO Not Empty Interrupt Enable
RFCLE	Receive FIFO Critical Level Interrupt Enable
NMVCE	Network Management Vector Changed Interrupt Enable
TIOE	Timer Interrupt 0 Enable
TI1E	Timer Interrupt 1 Enable
TIBCE	Transfer Input Buffer Completed Interrupt Enable
TOBCE	Transfer Output Buffer Completed Interrupt Enable
SWEE	Stop Watch Event Interrupt Enable
SUCSE	Startup Completed Successfully Interrupt Enable
MBSIE	Message Buffer Status Interrupt Enable
SDSE	Start of Dynamic Segment Interrupt Enable
WUPAE	Wakeup Pattern Channel A Interrupt Enable
MTSAE	MTS Received on Channel A Interrupt Enable
WUPBE	Wakeup Pattern Channel B Interrupt Enable
MTSBE	MTS Received on Channel B Interrupt Enable

#### 4.4.7 Interrupt Line Enable (ILE)

Each of the two interrupt lines to the Host (**eray\_int0**, **eray\_int1**) can be enabled / disabled separately by programming bit **EINT0** and **EINT1**.

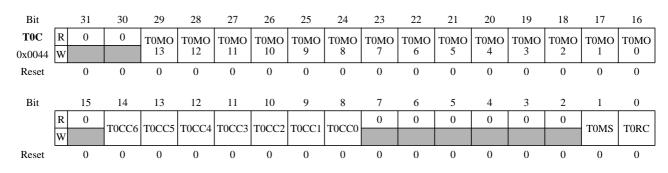

- **EINT0** Enable Interrupt Line 0
  - 1 = Interrupt line **eray\_int0** enabled
  - 0 = Interrupt line **eray\_int0** disabled
- **EINT1** Enable Interrupt Line 1
  - 1 = Interrupt line **eray\_int1** enabled
  - 0 = Interrupt line **eray\_int1** disabled

#### 4.4.8 Timer 0 Configuration (T0C)

Absolute timer. Specifies in terms of cycle count and macrotick the point in time when the timer 0 interrupt occurs. When the timer 0 interrupt is asserted, output signal **eray\_tint0** is set to '1' for the duration of one macrotick and **SIR.TI0** is set to '1'.

Timer 0 can be activated as long as the POC is either in NORMAL\_ACTIVE state or in NORMAL\_PASSIVE state. Timer 0 is deactivated when leaving NORMAL\_ACTIVE state or NORMAL\_PASSIVE state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing bit **TORC** to '0'.

**TORC** Timer 0 Run Control

- 1 = Timer 0 running
- 0 = Timer 0 halted

#### TOMS Timer 0 Mode Select

- 1 = Continuous mode
- 0 = Single-shot mode

#### T0CC[6:0] Timer 0 Cycle Code

The 7-bit timer 0 cycle code determines the cycle set used for generation of the timer 0 interrupt. For details about the configuration of the cycle code see Section 5.7.2 Cycle Counter Filtering.

#### T0MO[13:0] Timer 0 Macrotick Offset

Configures the macrotick offset from the beginning of the cycle where the interrupt is to occur. The Timer 0 Interrupt occurs at this offset for each cycle of the cycle set.

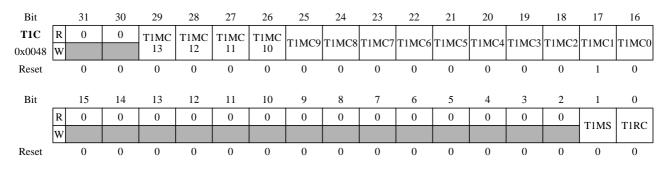

**Note:** The configuration of timer 0 is compared against the macrotick counter value, there is no separate counter for timer 0. In case the CC leaves NORMAL\_ACTIVE or NORMAL\_PASSIVE state, or if timer 0 is halted by Host command, output signal **eray\_tint0** is reset to '0' immediately.

# 4.4.9 Timer 1 Configuration (T1C)

Relative timer. After the specified number of macroticks has expired, the timer 1 interrupt is asserted, output signal **eray\_tint1** is set to '1' for the duration of one macrotick and **SIR.TI1** is set to '1'.

Timer 1 can be activated as long as the POC is either in NORMAL\_ACTIVE state or in NORMAL\_PASSIVE state. Timer 1 is deactivated when leaving NORMAL\_ACTIVE state or NORMAL\_PASSIVE state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing bit **T1RC** to '0'.

# T1RC Timer 1 Run Control

- 1 = Timer 1 running
- 0 = Timer 1 halted
- T1MS Timer 1 Mode Select
  - 1 = Continuous mode
  - 0 = Single-shot mode

T1MC[13:0] Timer 1 Macrotick Count

When the configured macrotick count is reached the timer 1 interrupt is generated.

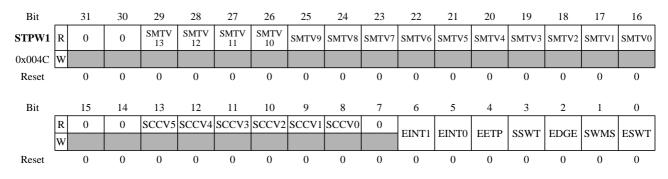

Valid values are: 2 to 16383 MT in continuous mode

1 to 16383 MT in single-shot mode

**Note:** In case the CC leaves NORMAL\_ACTIVE or NORMAL\_PASSIVE state, or if timer 1 is halted by Host command, output signal **eray\_tint1** is reset to '0' immediately.

# 4.4.10 Stop Watch Register 1 (STPW1)

The stop watch is activated by a rising or falling edge on pin **eray\_stpwt**, by an interrupt 0,1 event (rising edge on pin **eray\_int0** or **eray\_int1**) or by the Host by writing bit **SSWT** to '1'. With the macrotick counter increment following next to the stop watch activation the actual cycle counter and macrotick values are captured in register STPW1 while the slot counter values for channel A and B are captured in register STPW2.

# ESWT Enable Stop Watch Trigger

If enabled an edge on input **eray\_stpwt** or an interrupt 0,1 event (rising edge on pin **eray\_int0** or **eray\_int1**) activates the stop watch. In single-shot mode this bit is reset to '0' after the actual cycle counter and macrotick value are stored in the Stop Watch register.

1 = Stop watch trigger enabled

0 = Stop watch trigger disabled

- **SWMS** Stop Watch Mode Select
  - 1 = Continuous mode
  - 0 = Single-shot mode

EDGE Stop Watch Trigger Edge Select

- 1 = Rising edge
- 0 = Falling edge
- SSWT Software Stop Watch Trigger

When the Host writes this bit to '1' the stop watch is activated. After the actual cycle counter and macrotick value are stored in the Stop Watch register this bit is reset to '0'. The bit is only writeable while **ESWT** = '0'.

- 1 = Stop watch activated by software trigger
- 0 = Software trigger reset

# **EETP** Enable External Trigger Pin

Enables stop watch trigger event via pin **eray\_stpwt** if **ESWT** = '1'.

- 1 = Edge on pin **eray\_stpwt** triggers stop watch
- 0 = Stop watch trigger via pin **eray\_stpwt** disabled

# **EINT0** Enable Interrupt 0 Trigger

- Enables stop watch trigger by interrupt 0 event if ESWT = '1'.
- 1 = Interrupt 0 event triggers stop watch
- 0 = Stop watch trigger by interrupt 0 disabled

# EINT1 Enable Interrupt 1 Trigger

Enables stop watch trigger by interrupt levent if **ESWT** = '1'.

- 1 = Interrupt 1 event triggers stop watch
- 0 = Stop watch trigger by interrupt 1 disabled

SCCV[5:0] Stop Watch Captured Cycle Counter Value

State of the cycle counter when the stop watch event occurred. Valid values are 0 to 63.

**SMTV[13:0]** Stop Watch Captured Macrotick Value

State of the macrotick counter when the stop watch event occurred. Valid values are 0 to 16000.

**Note:** Bits **ESWT** and **SSWT** cannot be set to '1' simultaneously. In this case the write access is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

#### Bit SSCVB STPW2 R 0x0050 W Reset Bit SSCVA R W Reset

# 4.4.11 Stop Watch Register 2 (STPW2)

E-Ray

**SSCVA[10:0]** Stop Watch Captured Slot Counter Value Channel A

State of the slot counter for channel A when the stop watch event occurred. Valid values are 0 to 2047.

# **SSCVB[10:0]** Stop Watch Captured Slot Counter Value Channel B

State of the slot counter for channel B when the stop watch event occurred. Valid values are 0 to 2047.

# 4.5 CC Control Registers

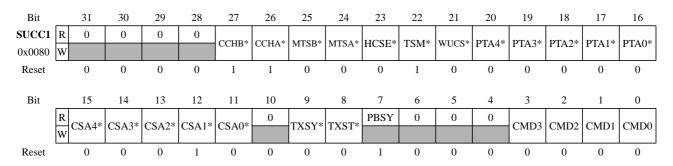

E-Ray

This section describes the registers provided by the CC to allow the Host to control the operation of the CC. The FlexRay protocol specification requires the Host to write application configuration data in CONFIG state only. Please consider that the configuration registers are not locked for writing in DEFAULT\_CONFIG state.

The configuration data is reset when DEFAULT\_CONFIG state is entered from hard reset. To change POC state from DEFAULT\_CONFIG to CONFIG state the Host has to apply CHI command CON-FIG. If the Host wants the CC to leave CONFIG state, the Host has to proceed as described in Section 4.3.1 Lock Register (LCK).

All bits marked with an asterisk \* can be updated in DEFAULT\_CONFIG or CONFIG state only!

# 4.5.1 SUC Configuration Register 1 (SUCC1)

CMD[3:0] CHI Command Vector

The Host may write any CHI command at any time, but certain commands are enabled only in certain POC states. If a command is not enabled, it will not be executed, the CHI command vector **CMD[3:0]** will be reset to "0000" = command\_not\_accepted, and flag **EIR.CNA** will be set to '1'. In case the previous CHI command has not yet completed, **EIR.CCL** is set to '1' together with **EIR.CNA**; the CHI command needs to be repeated. Except for HALT state, a POC state change command applied while the CC is already in the requested POC state will be ignored.

- 0000 = command\_not\_accepted
- 0001 = CONFIG
- 0010 = READY
- 0011 = WAKEUP
- 0100 = RUN
- 0101 = ALL\_SLOTS
- 0110 = HALT
- 0111 = FREEZE
- 1000 = SEND\_MTS
- 1001 = ALLOW\_COLDSTART
- 1010 = RESET\_STATUS\_INDICATORS
- 1011 = MONITOR\_MODE
- 1100 = CLEAR\_RAMS
- 1101 = reserved
- 1110 = reserved
- 1111 = reserved

Reading **CMD[3:0]** shows whether the last CHI command was accepted. The actual POC state is monitored by **CCSV.POCS[5:0]**. The reserved CHI commands belong to the hardware test functions.

#### command\_not\_accepted

**CMD[3:0]** is reset to "0000" due to one of the following conditions:

- Illegal command applied by the Host
- Host applied command to leave CONFIG state without preceding config lock key
- Host applied new command while execution of the previous Host command has not completed

#### • Host writes **command\_not\_accepted**

When **CMD**[3:0] is reset to "0000", **EIR.CNA** is set, and - if enabled - an interrupt is generated. Commands which are not accepted are not executed.

#### CONFIG

Go to POC state CONFIG when called in POC states DEFAULT\_CONFIG, READY, or in MONITOR\_MODE. When called in HALT state the CC transits to POC state DEFAULT\_CONFIG. When called in any other state, CMD[3:0] will be reset to "0000" = command\_not\_accepted.

#### READY

Go to POC state READY when called in POC states CONFIG, NORMAL\_ACTIVE, NORMAL\_PASSIVE, STARTUP, or WAKEUP. When called in any other state, **CMD[3:0]** will be reset to "0000" = command\_not\_accepted.

#### WAKEUP

Go to POC state WAKEUP when called in POC state READY. When called in any other state, **CMD[3:0]** will be reset to "0000" = command\_not\_accepted.

#### RUN

Go to POC state STARTUP when called in POC state READY. When called in any other state, **CMD[3:0]** will be reset to "0000" = command\_not\_accepted.

#### ALL\_SLOTS

Leave SINGLE slot mode after successful startup / integration at the next end of cycle when called in POC states NORMAL\_ACTIVE or NORMAL\_PASSIVE. When called in any other state, **CMD[3:0]** will be reset to "0000" = command\_not\_accepted.

#### HALT

Set halt request **CCSV.HRQ** and go to POC state HALT at the next end of cycle when called in POC states NORMAL\_ACTIVE or NORMAL\_PASSIVE. When called in any other state, **CMD[3:0]** will be reset to "0000" = command\_not\_accepted.

#### FREEZE

Set the freeze status indicator **CCSV.FSI** and go to POC state HALT immediately. Can be called from any state.

#### SEND\_MTS

Send single MTS symbol during the next following symbol window on the channel configured by **MTSA**, **MTSB**, when called in POC state NORMAL\_ACTIVE after CC entered ALL slot mode (**CCSV.SLM[1:0]** = "11"). When called in any other state, or when called while a previously requested MTS has not yet been transmitted, **CMD[3:0]** will be reset to "0000" = command\_not\_accepted.

E-Ray

# ALLOW\_COLDSTART

The command resets **CCSV.CSI** to enable the node to become leading coldstarter. When called in states DEFAULT\_CONFIG, CONFIG, HALT, or MONITOR\_MODE, **CMD[3:0]** will be reset to "0000" = command\_not\_accepted. To become leading coldstarter it is also required that both **TXST** and **TXSY** are set.

# **RESET\_STATUS\_INDICATORS**

Resets status flags **CCSV.CSNI**, **CCSV.CSAI**, and **CCSV.WSV[2:0]** to their default values. May be called in POC states READY and STARTUP. When called in any other state, **CMD[3:0]** will be reset to "0000" = command\_not\_accepted.

# MONITOR\_MODE

Enter MONITOR\_MODE when called in POC state CONFIG. In this mode the CC is able to receive FlexRay frames and wakeup pattern. It is also able to detect coding errors. The temporal integrity of received frames is not checked. This mode can be used for debugging purposes, e.g. in case that the startup of a FlexRay network fails. When called in any other state, **CMD[3:0]** will be reset to "0000" = command\_not\_accepted. For details see 5.5.4 MONITOR\_MODE

#### CLEAR\_RAMS

Sets **MHDS.CRAM** when called in DEFAULT\_CONFIG or CONFIG state. When called in any other state, **CMD[3:0]** will be reset to "0000" = command\_not\_accepted. **MHDS.CRAM** is also set when the CC leaves hard reset. By setting **MHDS.CRAM** all internal RAM blocks are initialized to zero. During the initialization of the RAMs, **PBSY** will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR\_RAMS.

The initialization of the E-Ray internal RAM blocks requires 2048 **eray\_bclk** cycles. There should be no Host access to IBF or OBF during initialization of the internal RAM blocks after hard reset or after assertion of CHI command CLEAR\_RAMS. Before asserting CHI command CLEAR\_RAMS the Host should make sure that no transfer between Message RAM and IBF / OBF or the Transient Buffer RAMs is ongoing. This command also resets the Message Buffer Status registers MHDS, LDTS, FSR, MHDF, TXRQ1/2/3/4, NDAT1/2/3/4, and MBSC1/2/3/4.

**Note:** All accepted commands with exception of CLEAR\_RAMS and SEND\_MTS will cause a change of register CCSV after at most 8 cycles of the slower of the two clocks **eray\_bclk** and **eray\_sclk**, counted from the falling edge of the CHI input signal **eray\_select**, assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time frame. Reading register CCSV will show data that is delayed by synchronization from **eray\_sclk** to **eray\_bclk** domain and by the Host-specific CPU interface.

# PBSY POC Busy

Signals that the POC is busy and cannot accept a command from the Host. **CMD[3:0]** is locked against write accesses. Set to '1' after hard reset during initialization of internal RAM blocks.

1 = POC is busy, **CMD**[3:0] locked

0 = POC not busy, **CMD[3:0]** writeable

#### **TXST** Transmit Startup Frame in Key Slot (pKeySlotUsedForStartup)

Defines whether the key slot is used to transmit startup frames. The bit can be modified in DEFAULT\_CONFIG or CONFIG state only.

- 1 = Key slot used to transmit startup frame, node is leading or following coldstarter
- 0 = No startup frame transmission in key slot, node is non-coldstarter

**TXSY** Transmit Sync Frame in Key Slot (pKeySlotUsedForSync)

Defines whether the key slot is used to transmit sync frames. The bit can be modified in DEFAULT\_CONFIG or CONFIG state only.

- 1 = Key slot used to transmit sync frame, node is sync node
- 0 = No sync frame transmission in key slot, node is neither sync nor coldstart node

**Note:** The protocol requires that both bits **TXST** and **TXSY** are set for coldstart nodes.

**CSA[4:0]** Cold Start Attempts (gColdStartAttempts)

Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node. It can be modified in DEFAULT\_CONFIG or CONFIG state only. Must be identical in all nodes of a cluster. Valid values are 2 to 31.

# **PTA[4:0]** Passive to Active (pAllowPassiveToActive)

Defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL\_PASSIVE to NORMAL\_ACTIVE state. If set to "00000" the CC is **not** allowed to transit from NORMAL\_PASSIVE to NORMAL\_ACTIVE state. It can be modified in DEFAULT\_CONFIG or CONFIG state only. Valid values are 0 to 31 even / odd cycle pairs.

# WUCS Wakeup Channel Select (pWakeupChannel)

With this bit the Host selects the channel on which the CC sends the Wakeup pattern. The CC ignores any attempt to change the status of this bit when not in DEFAULT\_CONFIG or CON-FIG state.

1 = Send wakeup pattern on channel B

0 = Send wakeup pattern on channel A

#### **TSM** Transmission Slot Mode (pSingleSlotEnabled)

Selects the initial transmission slot mode. In SINGLE slot mode the CC may only transmit in the preconfigured key slot. The key slot ID is configured in the header section of message buffer 0 respectively message buffers 0 and 1 depending on bit **MRC.SPLM**. In case **TSM** = '1', message buffer 0 respectively message buffers 0,1 can be (re)configured in DEFAULT\_CONFIG or CONFIG state only. In ALL slot mode the CC may transmit in all slots. **TSM** is a configuration bit which can only be set / reset by the Host. The bit can be written in DEFAULT\_CONFIG or CONFIG state only. The CC changes to ALL slot mode when the Host successfully applied the ALL\_SLOTS command by writing **CMD[3:0]** = "0101" in POC states NORMAL\_ACTIVE or NORMAL\_PASSIVE. The actual slot mode is monitored by **CCSV.SLM[1:0]**.

- 1 = SINGLE Slot Mode (default after hard reset)
- 0 = ALL Slot Mode

**HCSE** Halt due to Clock Sync Error (pAllowHaltDueToClock)

Controls the transition to HALT state due to a clock synchronization error. The bit can be modified in DEFAULT\_CONFIG or CONFIG state only.

- 1 = CC will enter HALT state
- 0 = CC will enter / remain in NORMAL\_PASSIVE

#### MTSA Select Channel A for MTS Transmission

The bit selects channel A for MTS symbol transmission. The flag is reset by default and may be modified only in DEFAULT\_CONFIG or CONFIG state.

- 1 = Channel A selected for MTS transmission
- 0 = Channel A disabled for MTS transmission

MTSB Select Channel B for MTS Transmission

The bit selects channel B for MTS symbol transmission. The flag is reset by default and may be modified only in DEFAULT\_CONFIG or CONFIG state.

- 1 = Channel B selected for MTS transmission
- 0 = Channel B disabled for MTS transmission

**Note: MTSA,B** may also be changed outside DEFAULT\_CONFIG or CONFIG state when the write to SUCC1 register is directly preceded by the unlock sequence as described in 4.3.1 Lock Register (LCK). This may be combined with CHI command SEND\_MTS. If both bits **MTSA** and **MTSB** are set to '1' an MTS symbol will be transmitted on both channels when requested by writing **CMD[3:0]** = "1000".

CCHA Connected to Channel A (pChannels)

Configures whether the node is connected to channel A.

- 1 = Node connected to channel A (default after hard reset)
- 0 = Not connected to channel A

**CCHB** Connected to Channel B (pChannels)

Configures whether the node is connected to channel B.

- 1 = Node connected to channel B (default after hard reset)
- 0 = Not connected to channel B

Table 3 below references the CHI commands from the FlexRay Protocol Specification v2.1 (section 2.2.1.1, Table 2-2) to the E-Ray CHI command vector CMD[3:0].

CHI command	Where processed (POC States)	CHI Command Vector CMD[3:0]
ALL_SLOTS	POC:normal active, POC:normal passive	ALL_SLOTS
ALLOW_COLDSTART	All except POC:default config, POC:config, POC:halt	ALLOW_COLDSTART
CONFIG	POC:default config, POC:ready	CONFIG
CONFIG_COMPLETE	POC:config	Unlock sequence & READY
DEFAULT_CONFIG	POC:halt	CONFIG
FREEZE	All	FREEZE
HALT	POC:normal active, POC:normal passive	HALT
READY	All except POC:default config, POC:config, POC:ready, POC:halt	READY
RUN	POC:ready	RUN
WAKEUP	POC:ready	WAKEUP

Table 3: Reference to CHI Host command summary from FlexRay protocol specification

# 4.5.2 SUC Configuration Register 2 (SUCC2)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

# LT[20:0] Listen Timeout (pdListenTimeout)

Configures wakeup / startup listen timeout in  $\mu$ T. The range for pdListenTimeout is 1284 to 1283846  $\mu$ T.

# **LTN[3:0]** Listen Timeout Noise (gListenNoise - 1)

Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of pdListenTimeout. The range for gListenNoise is 2 to 16. LTN[3:0] must be configured identical in all nodes of a cluster.

**Note:** The wakeup / startup noise timeout is calculated as follows: pdListenTimeout • gListenNoise = LT[20:0] • (LTN[3:0] + 1)

# 4.5.3 SUC Configuration Register 3 (SUCC3)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**WCP[3:0]** Maximum Without Clock Correction Passive (gMaxWithoutClockCorrectionPassive) Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL\_ACTIVE to NORMAL\_PASSIVE state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 cycle pairs.

WCF[3:0] Maximum Without Clock Correction Fatal (gMaxWithoutClockCorrectionFatal) Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL\_ACTIVE or NORMAL\_PASSIVE to HALT state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 cycle pairs.

# 4.5.4 NEM Configuration Register (NEMC)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

# TSST[3:0] Transmission Start Sequence Transmitter (gdTSSTransmitter)

Configures the duration of the Transmission Start Sequence (TSS) in terms of bit times (1 bit time =  $4 \mu T = 100$ ns @ 10Mbps). Must be identical in all nodes of a cluster. Valid values are 3 to 15 bit times.

# CASM[6:0] Collision Avoidance Symbol Max (gdCASRxLowMax)

Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS). **CASM6** is fixed to '1'. Valid values are 67 to 99 bit times.

# **SPP[1:0]** Strobe Point Position

Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by **SPP[1:0]**.

- 00, 11= Sample 5 (default)
- 01 =Sample 4
- 10 = Sample 6
- **Note:** The current revision 2.1 of the FlexRay protocol requires that **SPP[1:0]** = "00". The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.

# **BRP[1:0]** Baud Rate Prescaler (gdSampleClockPeriod, pSamplesPerMicrotick)

The Baud Rate Prescaler configures the baud rate on the FlexRay bus. The baud rates listed below are valid with a sample clock  $eray_sclk = 80$  MHz. One bit time always consists of 8 samples independent of the configured baud rate.

00 =	10 MBit/s (default)
	gdSampleClockPeriod = 12.5 ns = 1 • eray_sclk
	$pSamplesPerMicrotick = 2 (1 \mu T = 25 ns)$
01 =	5 MBit/s
	gdSampleClockPeriod = 25 ns = 2 • eray_sclk
	$pSamplesPerMicrotick = 1$ (1 $\mu$ T = 25 ns)
10, 11	= 2.5 MBit/s
	gdSampleClockPeriod = 50 ns = 4 • eray_sclk
	$pSamplesPerMicrotick = 1 (1 \mu T = 50 ns)$

**RXW[8:0]** Wakeup Symbol Receive Window Length (gdWakeupSymbolRxWindow)

Configures the number of bit times used by the node to test the duration of the received wakeup pattern. Must be identical in all nodes of a cluster. Valid values are 76 to 301 bit times.

# **RWP[5:0]** Repetitions of Tx Wakeup Pattern (pWakeupPattern)

Configures the number of repetitions (sequences) of the Tx wakeup symbol. Valid values are 2 to 63.

BOSCH

# 4.5.6 PRT Configuration Register 2 (PRTC2)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

# **RXI[5:0]** Wakeup Symbol Receive Idle (gdWakeupSymbolRxIdle)

Configures the number of bit times used by the node to test the duration of the idle phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 14 to 59 bit times.

# **RXL[5:0]** Wakeup Symbol Receive Low (gdWakeupSymbolRxLow)

Configures the number of bit times used by the node to test the duration of the low phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 10 to 55 bit times.

# **TXI[7:0]**Wakeup Symbol Transmit Idle (gdWakeupSymbolTxIdle)

Configures the number of bit times used by the node to transmit the idle phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 45 to 180 bit times.

# **TXL[5:0]**Wakeup Symbol Transmit Low (gdWakeupSymbolTxLow)

Configures the number of bit times used by the node to transmit the low phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 15 to 60 bit times.

# 4.5.7 MHD Configuration Register (MHDC)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

# **SFDL[6:0]** Static Frame Data Length (gPayloadLengthStatic)

Configures the cluster-wide payload length for all frames sent in the static segment in double bytes. The payload length must be identical in all nodes of a cluster. Valid values are 0 to 127.

# **SLT[12:0]** Start of Latest Transmit (pLatestTx)

Configures the maximum minislot value allowed before inhibiting frame transmission in the dynamic segment of the cycle. There is no transmission in dynamic segment if **SLT[12:0]** is set to zero. Valid values are 0 to 7981 minislots.

# 4.5.8 GTU Configuration Register 1 (GTUC1)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

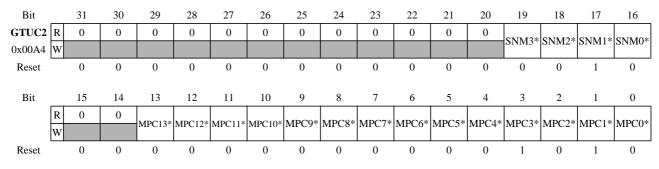

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

# **UT[19:0]** Microtick per Cycle (pMicroPerCycle)

Configures the duration of the communication cycle in microticks. Valid values are 640 to  $640000 \,\mu\text{T}$ .

# 4.5.9 GTU Configuration Register 2 (GTUC2)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

# MPC[13:0] Macrotick Per Cycle (gMacroPerCycle)

Configures the duration of one communication cycle in macroticks. The cycle length must be identical in all nodes of a cluster. Valid values are 10 to 16000 MT.

# **SNM[3:0]** Sync Node Max (gSyncNodeMax)

Maximum number of frames within a cluster with sync frame indicator bit **SYN** set to '1'. Must be identical in all nodes of a cluster. Valid values are 2 to 15.

# 4.5.10 GTU Configuration Register 3 (GTUC3)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

# **UIOA[7:0]** Microtick Initial Offset Channel A (pMicroInitialOffset[A])

Configures the number of microticks between the actual time reference point on channel A and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[A] and therefore has to be set for each channel independently. Valid values are 0 to 240  $\mu$ T.

#### **UIOB[7:0]** Microtick Initial Offset Channel B (pMicroInitialOffset[B])

Configures the number of microticks between the actual time reference point on channel B and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[B] and therefore has to be set for each channel independently. Valid values are 0 to 240  $\mu$ T.

# MIOA[6:0] Macrotick Initial Offset Channel A (pMacroInitialOffset[A])

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 MT.

#### MIOB[6:0] Macrotick Initial Offset Channel B (pMacroInitialOffset[B])

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 MT.

# 4.5.11 GTU Configuration Register 4 (GTUC4)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only. For details about configuration of **NIT[13:0]** and **OCS[13:0]** see Section 5.1.5 Configuration of NIT Start and Offset Correction Start.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

# **NIT[13:0]** Network Idle Time Start (gMacroPerCycle - gdNIT - 1)

Configures the starting point of the Network Idle Time NIT at the end of the communication cycle expressed in terms of macroticks from the beginning of the cycle. The start of NIT is recognized if Macrotick = gMacroPerCycle - gdNIT - 1 and the increment pulse of Macrotick is set. Must be identical in all nodes of a cluster. Valid values are 7 to 15997 MT.

# **OCS**[13:0] Offset Correction Start (gOffsetCorrectionStart - 1)

Determines the start of the offset correction within the NIT phase, calculated from start of cycle. Must be identical in all nodes of a cluster. For cluster consisting of E-Ray implementations only, it is sufficient to program OCS = NIT + 1. Valid values are 8 to 15998 MT.

# 4.5.12 GTU Configuration Register 5 (GTUC5)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

# **DCA[7:0]** Delay Compensation Channel A (pDelayCompensation[A])

Used to compensate for reception delays on the indicated channel. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05 $\mu$ s. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200  $\mu$ T.

# **DCB[7:0]** Delay Compensation Channel B (pDelayCompensation[B])

Used to compensate for reception delays on the indicated channel. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05 $\mu$ s. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200  $\mu$ T.

# **CDD[4:0]** Cluster Drift Damping (pClusterDriftDamping)

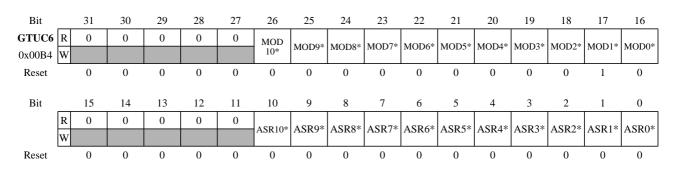

Configures the cluster drift damping value used in clock synchronization to minimize accumulation of rounding errors. Valid values are 0 to  $20 \,\mu$ T.

# **DEC**[7:0] Decoding Correction (pDecodingCorrection)

Configures the decoding correction value used to determine the primary time reference point. Valid values are 14 to 143  $\mu$ T.

# 4.5.13 GTU Configuration Register 6 (GTUC6)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

# ASR[10:0] Accepted Startup Range (pdAcceptedStartupRange)

Number of microticks constituting the expanded range of measured deviation for startup frames during integration. Valid values are 0 to 1875  $\mu$ T.

# MOD[10:0] Maximum Oscillator Drift (pdMaxDrift)

Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in  $\mu$ T. Valid values are 2 to 1923  $\mu$ T.

# 4.5.14 GTU Configuration Register 7 (GTUC7)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

# **SSL[9:0]** Static Slot Length (gdStaticSlot)

Configures the duration of a static slot in macroticks. The static slot length must be identical in all nodes of a cluster. Valid values are 4 to 659 MT.

# **NSS[9:0]** Number of Static Slots (gNumberOfStaticSlots)

Configures the number of static slots in a cycle. At least 2 coldstart nodes must be configured to startup a FlexRay network. The number of static slots must be identical in all nodes of a cluster. Valid values are 2 to 1023.

# 4.5.15 GTU Configuration Register 8 (GTUC8)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

# APO[5:0] Action Point Offset (gdActionPointOffset)

Configures the action point offset in macroticks within static slots and symbol window. Must be identical in all nodes of a cluster. Valid values are 1 to 63 MT.

# MAPO[4:0] Minislot Action Point Offset (gdMinislotActionPointOffset)

Configures the action point offset in macroticks within the minislots of the dynamic segment. Must be identical in all nodes of a cluster. Valid values are 1 to 31 MT.

# **DSI[1:0]** Dynamic Slot Idle Phase (gdDynamicSlotIdlePhase)

The duration of the dynamic slot idle phase has to be greater or equal than the idle detection time. Must be identical in all nodes of a cluster. Valid values are 0 to 2 Minislot.

# 4.5.17 GTU Configuration Register 10 (GTUC10)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

# nanual\_programmers\_model.fm

# MOC[13:0] Maximum Offset Correction (pOffsetCorrectionOut)

Holds the maximum permitted offset correction value to be applied by the internal clock synchronization algorithm (absolute value). The CC checks only the internal offset correction value against the maximum offset correction value. Valid values are 5 to 15266  $\mu$ T.

# MRC[10:0] Maximum Rate Correction (pRateCorrectionOut)

Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The CC checks only the internal rate correction value against the maximum rate correction value (absolute value). Valid values are 2 to 1923  $\mu$ T.

# 4.5.18 GTU Configuration Register 11 (GTUC11)

EOCC[1:0] External Offset Correction Control (vExternOffsetControl)

By writing to **EOCC[1:0]** the external offset correction is enabled as specified below. Should be modified only outside NIT.

- 00, 01 = No external offset correction
- 10 = External offset correction value subtracted from calculated offset correction value
- 11 = External offset correction value added to calculated offset correction value

# ERCC[1:0] External Rate Correction Control (vExternRateControl)

By writing to **ERCC[1:0]** the external rate correction is enabled as specified below. Should be modified only outside NIT.

- 00, 01 = No external rate correction
- 10 = External rate correction value subtracted from calculated rate correction value
- 11 = External rate correction value added to calculated rate correction value

# **EOC[2:0]** External Offset Correction (pExternOffsetCorrection)

Holds the external offset correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated offset correction value. The value is applied during NIT. May be modified in DEFAULT\_CONFIG or CONFIG state only. Valid values are 0 to 7  $\mu$ T.

# **ERC[2:0]** External Rate Correction (pExternRateCorrection)

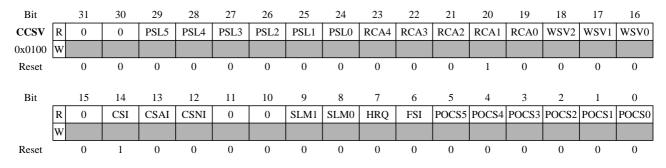

Holds the external rate correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated rate correction value. The value is applied during NIT. May be modified in DEFAULT\_CONFIG or CONFIG state only. Valid values are 0 to 7  $\mu$ T.

# 4.6 CC Status Registers

E-Ray

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the CC between two accesses (non-atomic read accesses). The status vector may change faster than the Host can poll the status vector, depending on **eray\_bclk** frequency.

# 4.6.1 CC Status Vector (CCSV)

**POCS**[5:0] Protocol Operation Control Status

Indicates the actual state of operation of the CC Protocol Operation Control

- 00 0000 = DEFAULT\_CONFIG state
- $00\ 0001 = READY$  state
- 00 0010 = NORMAL\_ACTIVE state
- 00 0011 = NORMAL\_PASSIVE state
- $00\ 0100 =$  HALT state
- 00 0101 = MONITOR\_MODE state
- $00\ 0110\dots 00\ 1110 = reserved$
- $00\ 1111 = \text{CONFIG state}$

Indicates the actual state of operation of the POC in the wakeup path

- 01 0000 = WAKEUP\_STANDBY state
- 01 0001 = WAKEUP\_LISTEN state
- 01 0010 = WAKEUP\_SEND state
- 01 0011 = WAKEUP\_DETECT state
- 01 0100...01 1111 = reserved

Indicates the actual state of operation of the POC in the startup path

- 10 0000 = STARTUP\_PREPARE state
- 10 0001 = COLDSTART\_LISTEN state
- 10 0010 = COLDSTART\_COLLISION\_RESOLUTION state
- 10 0011 = COLDSTART\_CONSISTENCY\_CHECK state
- 10 0100 = COLDSTART\_GAP state
- 10 0101 = COLDSTART\_JOIN State
- 10 0110 = INTEGRATION\_COLDSTART\_CHECK state
- 10 0111 = INTEGRATION\_LISTEN state
- 10 1000 = INTEGRATION\_CONSISTENCY\_CHECK state
- 10 1001 = INITIALIZE\_SCHEDULE state
- 10 1010 = ABORT\_STARTUP state
- 10 1011 = STARTUP\_SUCCESS state
- 10 1100...11 1111 = reserved

🖨) BOSCH

FSI Freeze Status Indicator (vPOC!Freeze)

Indicates that the POC has entered the HALT state due to CHI command FREEZE or due to an error condition requiring an immediate POC halt. Reset by transition from HALT to DEFAULT\_CONFIG state.

# HRQ Halt Request (vPOC!CHIHaltRequest)

Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle. Reset by transition from HALT to DEFAULT\_CONFIG state or when entering READY state.

# SLM[1:0] Slot Mode (vPOC!SlotMode)

Indicates the actual slot mode of the POC in states READY, STARTUP, NORMAL\_ACTIVE, and NORMAL\_PASSIVE. Default is SINGLE. Changes to ALL, depending on **SUCC1.TSM**. In NORMAL\_ACTIVE or NORMAL\_PASSIVE state the CHI command ALL\_SLOTS will change the slot mode from SINGLE over ALL\_PENDING to ALL. Set to SINGLE in all other states.

00 = SINGLE

01 = reserved

10 = ALL\_PENDING

11 = ALL

#### CSNI Coldstart Noise Indicator (vPOC!ColdstartNoise)

Indicates that the cold start procedure occurred under noisy conditions. Reset by CHI command RESET\_STATUS\_INDICATORS or by transition from HALT to DEFAULT\_CONFIG state or from READY to STARTUP state.

#### CSAI Coldstart Abort Indicator

Coldstart aborted. Reset by CHI command RESET\_STATUS\_INDICATORS or by transition from HALT to DEFAULT\_CONFIG state or from READY to STARTUP state.

# CSI Cold Start Inhibit (vColdStartInhibit)

Indicates that the node is disabled from cold starting. The flag is set whenever the POC enters READY state due to CHI command READY. The flag has to be reset under control of the Host by CHI command ALLOW\_COLDSTART (**SUCC1.CMD[3:0]** = "1001").

1 = Cold starting of node disabled

0 = Cold starting of node enabled

WSV[2:0] Wakeup Status (vPOC!WakeupStatus)

Indicates the status of the current wakeup attempt. Reset by CHI command RESET\_STATUS\_INDICATORS or by transition from HALT to DEFAULT\_CONFIG state or from READY to STARTUP state.

- 000 = UNDEFINED. Wakeup not yet executed by the CC.
- 001 = RECEIVED\_HEADER. Set when the CC finishes wakeup due to the reception of a frame header without coding violation on either channel in WAKEUP\_LISTEN state.
- 010 = RECEIVED\_WUP. Set when the CC finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in WAKEUP\_LISTEN state.
- 011 = COLLISION\_HEADER. Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid header on either channel.
- 100 = COLLISION\_WUP. Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel.
- 101 = COLLISION\_UNKNOWN. Set when the CC stops wakeup by leaving WAKEUP\_DETECT state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid frame header.
- 110 = TRANSMITTED. Set when the CC has successfully completed the transmission of the wakeup pattern.
- 111 = reserved

# **RCA[4:0]** Remaining Coldstart Attempts (vRemainingColdstartAttempts)

Indicates the number of remaining coldstart attempts. The RUN command resets this counter to the maximum number of coldstart attempts as configured by **SUCC1.CSA[4:0]**.

# PSL[5:0] POC Status Log

Status of POCS[5:0] immediately before entering HALT state. Set when entering HALT state. Set to HALT when FREEZE command is applied during HALT state. Reset to "00 0000" when leaving HALT state.

Reset by transition from HALT to DEFAULT\_CONFIG state or when entering READY state.

# CCFC[3:0] Clock Correction Failed Counter (vClockCorrectionFailed)

The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active. The Clock Correction Failed Counter is reset to '0' at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active. The Clock Correction Failed Counter stops at 15.

ERRM[1:0] Error Mode (vPOC!ErrorMode)

Indicates the actual error mode of the POC.

- 00 = ACTIVE (green)
- 01 = PASSIVE (yellow)
- $10 = \text{COMM}_\text{HALT} (\text{red})$
- 11 = reserved

#### **PTAC[4:0]** Passive to Active Count (vAllowPassiveToActive)

Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from NORMAL\_PASSIVE state to NORMAL\_ACTIVE state. The transition takes place when **PTAC[4:0]** equals **SUCC1.PTA[4:0] -1**.

# 4.6.3 Slot Counter Value (SCV)

# **SCCA[10:0]** Slot Counter Channel A (vSlotCounter[A])

Current slot counter value on channel A. The value is incremented by the CC and reset at the start of a communication cycle. Valid values are 0 to 2047.

#### **SCCB[10:0]** Slot Counter Channel B (vSlotCounter[B])

Current slot counter value on channel B. The value is incremented by the CC and reset at the start of a communication cycle. Valid values are 0 to 2047.

# 4.6.5 Rate Correction Value (RCV)

# **RCV[11:0]** Rate Correction Value (vRateCorrection)

Rate correction value (two's complement). Calculated internal rate correction value **before** limitation. If the RCV value exceeds the limits defined by **GTUC10.MRC[10:0]**, flag **SFS.RCLR** is set to '1'.

# 4.6.6 Offset Correction Value (OCV)

#### OCV[18:0] Offset Correction Value (vOffsetCorrection)

Offset correction value (two's complement). Calculated internal offset correction value **before** limitation. If the OCV value exceeds the limits defined by **GTUC10.MOC[13:0]**, flag **SFS.OCLR** is set to '1'.

**Note:** The external rate / offset correction value is added to the limited rate / offset correction value.

# 4.6.7 Sync Frame Status (SFS)

The maximum number of valid sync frames in a communication cycle is 15.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	W																
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### VSAE[3:0] Valid Sync Frames Channel A, even communication cycle

Holds the number of valid sync frames received on channel A in the even communication cycle. If transmission of sync frames is enabled by **SUCC1.TXSY** the value is incremented by one. The value is updated during the NIT of each even communication cycle.

**VSAO[3:0]** Valid Sync Frames Channel A, **odd** communication cycle

Holds the number of valid sync frames received on channel A in the odd communication cycle. If transmission of sync frames is enabled by **SUCC1.TXSY** the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

# VSBE[3:0] Valid Sync Frames Channel B, even communication cycle

Holds the number of valid sync frames received on channel B in the even communication cycle. If transmission of sync frames is enabled by **SUCC1.TXSY** the value is incremented by one. The value is updated during the NIT of each even communication cycle.

#### VSBO[3:0] Valid Sync Frames Channel B, odd communication cycle

Holds the number of valid sync frames received on channel B in the odd communication cycle. If transmission of sync frames is enabled by **SUCC1.TXSY** the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

**Note:** The bit fields above are only valid if the respective channel is assigned to the CC by **SUCC1.CCHA** or **SUCC1.CCHB**.

# MOCS Missing Offset Correction Signal

The Missing Offset Correction flag signals to the Host, that no offset correction calculation can be performed because no sync frames were received. The flag is updated by the CC at start of offset correction phase.

- 1 = Missing offset correction signal
- 0 = Offset correction signal valid

# OCLR Offset Correction Limit Reached

The Offset Correction Limit Reached flag signals to the Host, that the offset correction value has exceeded its limit as defined by **GTUC10.MOC**[13:0]. The flag is updated by the CC at start of offset correction phase.

- 1 = Offset correction limit reached
- 0 = Offset correction below limit

# MRCS Missing Rate Correction Signal

The Missing Rate Correction flag signals to the Host, that no rate correction calculation can be performed because no pairs of even / odd sync frames were received. The flag is updated by the CC at start of offset correction phase.

- 1 = Missing rate correction signal
- 0 = Rate correction signal valid

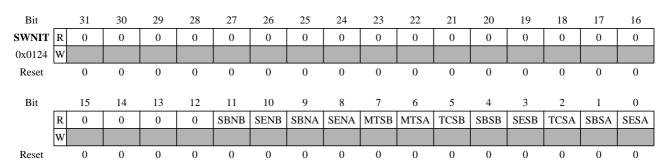

# **RCLR** Rate Correction Limit Reached

The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit as defined by **GTUC10.MRC[10:0]**. The flag is updated by the CC at start of offset correction phase.

1 = Rate correction limit reached

0 = Rate correction below limit

# 4.6.8 Symbol Window and NIT Status (SWNIT)

Symbol window related status information. Updated by the CC at the end of the symbol window for each channel. During startup the status data is not updated.

- **SESA** Syntax Error in Symbol Window Channel A (vSS!SyntaxErrorA)
  - 1 = Syntax error during symbol window detected on channel A
  - 0 = No syntax error detected

# **SBSA** Slot Boundary Violation in Symbol Window Channel A (vSS!BViolationA)

- 1 = Slot boundary violation during symbol window detected on channel A
- 0 = No slot boundary violation detected
- TCSA Transmission Conflict in Symbol Window Channel A (vSS!TxConflictA)
  - 1 = Transmission conflict in symbol window detected on channel A
  - 0 = No transmission conflict detected

# Syntax Error in Symbol Window Channel B (vSS!SyntaxErrorB)

- 1 = Syntax error during symbol window detected on channel B
- 0 = No syntax error detected

# **SBSB** Slot Boundary Violation in Symbol Window Channel B (vSS!BViolationB)

- 1 = Slot boundary violation during symbol window detected on channel B
- 0 = No slot boundary violation detected

# **TCSB** Transmission Conflict in Symbol Window Channel B (vSS!TxConflictB)

- 1 = Transmission conflict in symbol window detected on channel B
- 0 = No transmission conflict detected

**SESB** 

MTSA MTS Received on Channel A (vSS!ValidMTSA)

Media Access Test symbol received on channel A during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window. When this bit is set to '1', also interrupt flag **SIR.MTSA** is set to '1'.

- 1 = MTS symbol received on channel A
- 0 = No MTS symbol received on channel A
- MTSB MTS Received on Channel B (vSS!ValidMTSB)

Media Access Test symbol received on channel B during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window. When this bit is set to '1', also interrupt flag **SIR.MTSB** is set to '1'.

- 1 = MTS symbol received on channel B
- 0 = No MTS symbol received on channel B

NIT related status information. Updated by the CC at the end of the NIT for each channel:

- **SENA** Syntax Error during NIT Channel A (vSS!SyntaxErrorA)
  - 1 = Syntax error during NIT detected on channel A
  - 0 = No syntax error detected

# **SBNA** Slot Boundary Violation during NIT Channel A (vSS!BViolationA)

- 1 = Slot boundary violation during NIT detected on channel A
- 0 = No slot boundary violation detected
- **SENB** Syntax Error during NIT Channel B (vSS!SyntaxErrorB)
  - 1 = Syntax error during NIT detected on channel B
  - 0 = No syntax error detected
- **SBNB** Slot Boundary Violation during NIT Channel B (vSS!BViolationB)
  - 1 = Slot boundary violation during NIT detected on channel B
  - 0 = No slot boundary violation detected

# 4.6.9 Aggregated Channel Status (ACS)

The aggregated channel status provides the Host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception. The aggregated channel status also includes status data from the symbol window and the network idle time. The status data is updated (set) after each slot and aggregated until it is reset by the Host. During startup the status data is not updated. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect on the flag. A hard reset will also clear the register.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

# **VFRA** Valid Frame Received on Channel A (vSS!ValidFrameA)

One or more valid frames were received on channel A in any static or dynamic slot during the observation period.

- 1 = Valid frame(s) received on channel A
- 0 = No valid frame received

# **SEDA** Syntax Error Detected on Channel A (vSS!SyntaxErrorA)

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel A.

- 1 = Syntax error(s) observed on channel A
- 0 = No syntax error observed

# CEDA Content Error Detected on Channel A (vSS!ContentErrorA)

One or more frames with a content error were received on channel A in any static or dynamic slot during the observation period.

- 1 =Frame(s) with content error received on channel A
- 0 = No frame with content error received
- CIA Communication Indicator Channel A

One or more valid frames were received on channel A in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.

- 1 = Valid frame(s) received on channel A in slots containing any additional communication
- 0 = No valid frame(s) received in slots containing any additional communication

# **SBVA** Slot Boundary Violation on Channel A (vSS!BViolationA)

One or more slot boundary violations were observed on channel A at any time during the observation period (static or dynamic slots, symbol window, and NIT).

- 1 = Slot boundary violation(s) observed on channel A
- 0 = No slot boundary violation observed

**VFRB** Valid Frame Received on Channel B (vSS!ValidFrameB)

One or more valid frames were received on channel B in any static or dynamic slot during the observation period. Reset under control of the Host.

- 1 = Valid frame(s) received on channel B
- 0 = No valid frame received

**SEDB** Syntax Error Detected on Channel B (vSS!SyntaxErrorB)

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel B.

- 1 = Syntax error(s) observed on channel B
- 0 = No syntax error observed
- **CEDB** Content Error Detected on Channel B (vSS!ContentErrorB)

One or more frames with a content error were received on channel B in any static or dynamic slot during the observation period.

- 1 = Frame(s) with content error received on channel B
- 0 = No frame with content error received
- CIB Communication Indicator Channel B

One or more valid frames were received on channel B in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.

- 1 = Valid frame(s) received on channel B in slots containing any additional communication
- 0 = No valid frame(s) received in slots containing any additional communication

# **SBVB** Slot Boundary Violation on Channel B (vSS!BViolationB)

One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots, symbol window, and NIT).

- 1 = Slot boundary violation(s) observed on channel B
- 0 = No slot boundary violation observed
- **Note:** The set condition of flags **CIA** and **CIB** is also fulfilled if there is only one single frame in the slot and the slot boundary at the end of the slot is reached during the frames channel idle recognition phase.

When one of the flags **SEDB**, **CEDB**, **CIB**, **SBVB** changes from '0' to '1', interrupt flag **EIR.EDB** is set to '1'.When one of the flags **SEDA**, **CEDA**, **CIA**, **SBVA** changes from '0' to '1', interrupt flag **EIR.EDA** is set to '1'.

# 4.6.10 Even Sync ID [1...15] (ESIDn)

Registers ESID1 to ESID15 hold the frame IDs of the sync frames received in **even** communication cycles, sorted in ascending order, with register ESID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an even communication cycle, register ESID1 holds the respective sync frame ID as configured in message buffer 0 and flags **RXEA**, **RXEB** are set. The value is updated during the NIT of each even communication cycle.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

# **EID[9:0]** Even Sync ID (vsSyncIDListA, B even)

Sync frame ID even communication cycle.

**RXEA** Received / Configured Even Sync ID on Channel A

Signals that a sync frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = EID[9:0] (ESID1 only).

- 1 = Sync frame received on channel A / node configured to transmit sync frames
- 0 = No sync frame received on channel A / node not configured to transmit sync frames

# **RXEB** Received / Configured Even Sync ID on Channel B

Signals that a sync frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot = EID[9:0] (ESID1 only).

1 = Sync frame received on channel B / node configured to transmit sync frames

0 = No sync frame received on channel B / node not configured to transmit sync frames

manual\_programmers\_model.fm

# 4.6.11 Odd Sync ID [1...15] (OSIDn)

Registers OSID1 to OSID15 hold the frame IDs of the sync frames received in **odd** communication cycles, sorted in ascending order, with register OSID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an odd communication cycle, register OSID1 holds the respective sync frame ID as configured in message buffer 0 and flags **RXOA**, **RXOB** are set. The value is updated during the NIT of each odd communication cycle.

# OID[9:0] Odd Sync ID (vsSyncIDListA,B odd)

Sync frame ID odd communication cycle.

**RXOA** Received / Configured Odd Sync ID on Channel A

Signals that a sync frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = **OID**[9:0] (OSID1 only).

- 1 = Sync frame received on channel A / node configured to transmit sync frames
- 0 = No sync frame received on channel A / node not configured to transmit sync frames

# **RXOB** Received / Configured Odd Sync ID on Channel B

Signals that a sync frame corresponding to the stored odd sync ID was received on channel B or that the node is configured to be a sync node with key slot = **OID[9:0]** (OSID1 only).

1 = Sync frame received on channel B / node configured to transmit sync frames

0 = No sync frame received on channel B / node not configured to transmit sync frames

manual\_programmers\_model.fm

# 4.6.12 Network Management Vector [1...3] (NMVn)

The three network management registers hold the accrued NM vector (configurable 0 to 12 bytes). The accrued NM vector is generated by the CC by bit-wise ORing each NM vector received (valid static frames with PPI = '1') on each channel (see 5.6 Network Management).

The CC updates the NM vector at the end of each communication cycle as long as the CC is either in NORMAL\_ACTIVE or NORMAL\_PASSIVE state.

NMVn-bytes exceeding the configured NM vector length are not valid.

Table 4: Assignment of data bytes to network management vector

# 4.7 Message Buffer Control Registers

# 4.7.1 Message RAM Configuration (MRC)

The Message RAM Configuration register defines the number of message buffers assigned to the static segment, dynamic segment, and FIFO. The register can be written during DEFAULT\_CONFIG or CONFIG state only.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MRC	R	0	0	0	0	0	SPLM*	SEC1*	SEC0*	LCB7*	LCB6*	LCB5*	LCB4*	LCB3*	LCB2*	LCB1*	LCB0*
0x0300	W		0			0											
Reset		0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0
Bit	_	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	R W	FFB7*	FFB6*	FFB5*	FFB4*	FFB3*	FFB2*	FFB1*	FFB0*	FDB7*	FDB6*	FDB5*	FDB4*	FDB3*	FDB2*	FDB1*	FDB0*
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
11 ≥ <b>FFB[7</b> 11 ≥	<ul> <li>FDB[7:0] First Dynamic Buffer</li> <li>0 = No group of message buffers exclusively for the static segment configured</li> <li>1127 = Message buffers 0 to FDB - 1 reserved for static segment</li> <li>≥128 = No dynamic message buffers configured</li> <li>FFB[7:0] First Buffer of FIFO</li> <li>0 = All message buffers assigned to the FIFO</li> <li>1127 = Message buffers from FFB to LCB assigned to the FIFO</li> <li>≥128 = No message buffer assigned to the FIFO</li> <li>≥128 = No message buffer assigned to the FIFO</li> <li>≥128 = No message buffer assigned to the FIFO</li> </ul>																
01	<b>LCB</b> [7:0] Last Configured Buffer 0127 = Number of message buffers is <b>LCB</b> + 1 $\geq 128 =$ No message buffer configured																
N 00 01	SEC[1:0] Secure Buffers Not evaluated when the CC is in DEFAULT_CONFIG or CONFIG state. 00 = Reconfiguration of message buffers enabled with numbers < FFB enabled Exception: In nodes configured for sync frame transmission or for single slot mode opera- tion message buffer 0 (and if SPLM = '1', also message buffer 1) is always locked 01 = Reconfiguration of message buffers with numbers < FDB and with numbers ≥ FFB locked and transmission of message buffers for static segment with numbers ≥ FDB disabled 10 = Reconfiguration of all message buffers locked 11 = Reconfiguration of all message buffers locked and transmission of message buffers for static segment with numbers ≥ FDB disabled																
Ti si ar W lo m	SPLM Sync Frame Payload Multiplex This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = '1') or for single slot mode operation (SUCC1.TSM = '1'). When this bit is set to '1' message buffers 0 and 1 are dedicated for sync frame transmission with different payload data on channel A and B. When this bit is set to '0', sync frames are transmitted from message buffer 0 with the same pay- load data on both channels. Note that the channel filter configuration for message buffer 0 resp. message buffer 1 has to be chosen accordingly. 1 = Both message buffers 0 and 1 are locked against reconfiguration																

0 = Only message buffer 0 locked against reconfiguration

**Note:** In case the node is configured as sync node (**SUCC1.TXSY** = '1') or for single slot mode operation (**SUCC1.TSM** = '1'), message buffer 0 resp. 1 is reserved for sync frames or single slot frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation message buffer 0 resp. 1 is treated like all other message buffers.

Message Buffer 0	↓ Static Buffers		
Message Buffer 1	]		
	↓ Static + Dynamic Buffers ↓ FIFO	⇐ FDB ⇐ FFB	FIFO configured: <b>FFB</b> > <b>FDB</b> No FIFO configured: <b>FFB</b> ≥ 128
Message Buffer N-1			
Message Buffer N		⇐ LCB	$\textbf{LCB} \geq \textbf{FDB},  \textbf{LCB} \geq \textbf{FFB}$

The programmer has to ensure that the configuration defined by **FDB**[7:0], **FFB**[7:0], and **LCB**[7:0] is valid. The CC does not check for erroneous configurations!

**Note:** The maximum number of header sections is 128. This means a maximum of 128 message buffers can be configured. The maximum length of a data section is 254 bytes. The length of the data section may be configured differently for each message buffer. For details see Section 5.12 Message RAM.

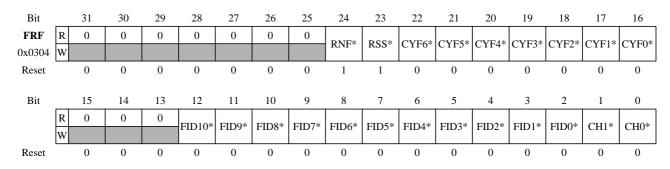

In case two or more message buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the "Static Buffers" or at the beginning of the "Static + Dynamic Buffers" section.

The payload length configured and the length of the data section need to be configured identical for all message buffers belonging to the FIFO via **WRHS2.PLC[6:0]** and **WRHS3.DP[10:0]**. When the CC is not in DEFAULT\_CONFIG or CONFIG state reconfiguration of message buffers belonging to the FIFO is locked.

## 4.7.2 FIFO Rejection Filter (FRF)

E-Ray

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, frame ID, and cycle count of the incoming frames are compared. Together with the FIFO Rejection Filter Mask this register determines whether a message is rejected by the FIFO. The FRF register can be written during DEFAULT\_CONFIG or CONFIG state only.

#### CH[1:0] Channel Filter

- 11 = no reception
- 10 = receive only on channel A
- 01 = receive only on channel B
- 00 = receive on both channels
- **Note:** If reception on both channels is configured, also in static segment always both frames (from channel A and B) are stored in the FIFO, even if they are identical.

#### FID[10:0] Frame ID Filter

Determines the frame ID to be rejected by the FIFO. With the additional configuration of register FRFM, the corresponding frame ID filter bits are ignored, which results in further rejected frame IDs. When **FRFM.MFID[10:0]** is zero, a frame ID filter value of zero means that **no** frame ID is rejected.

0...2047 = Frame ID filter values

### **CYF[6:0]** Cycle Counter Filter

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles **not** belonging to the cycle set specified by **CYF[6:0]**, all frames are rejected. For details about the configuration of the cycle counter filter see Section 5.7.2 Cycle Counter Filtering.

#### **RSS** Reject in Static Segment

If this bit is set, the FIFO is used only for the dynamic segment.

- 1 = Reject messages in static segment
- 0 = FIFO also used for static segment

### **RNF** Reject Null Frames

If this bit is set, received null frames are not stored in the FIFO.

- 1 = Reject all null frames
- 0 = Null frames are stored in the FIFO

## 4.7.3 FIFO Rejection Filter Mask (FRFM)

The FIFO Rejection Filter Mask specifies which of the corresponding frame ID filter bits are relevant for rejection filtering. If a bit is set, it indicates that the corresponding bit in the FRF register will not be considered for rejection filtering. The FRFM register can be written during DEFAULT\_CONFIG or CONFIG state only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FRFM R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
0x0308 W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	MFID	0	0										
W				10*	9*	8*	7*	6*	5*	4*	3*	2*	1*	0*		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### MFID[10:0] Mask Frame ID Filter

1 = Ignore corresponding frame ID filter bit.

0 = Corresponding frame ID filter bit is used for rejection filtering

## 4.7.4 FIFO Critical Level (FCL)

The CC accepts modifications of the register in DEFAULT\_CONFIG or CONFIG state only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FCL R	. 0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
0x030C W	7															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	. 0	0	0	0	0	0	0	0	CL7*	CL6*	CL5*	CL4*	CL3*	CL2*	CL1*	CL0*
W	7										CL3*	CL4*	CL3*	CL2*	CL1*	
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

## CL[7:0] Critical Level

When the receive FIFO fill level **FSR.RFFL**[7:0] is equal or greater than the critical level configured by **CL**[7:0], the receive FIFO critical level flag **FSR.RFCL** is set. If **CL**[7:0] is programmed to values > 128, bit **FSR.RFCL** is never set. When **FSR.RFCL** changes from '0' to '1' bit **SIR.RFCL** is set to '1', and if enabled, an interrupt is generated.

#### E-Ray

## 4.8 Message Buffer Status Registers

### 4.8.1 Message Handler Status (MHDS)

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MHDS	R	0	MBU6	MBU5	MBU4	MBU3	MBU2	MBU1	MBU0	0	MBT6	MBT5	MBT4	MBT3	MBT2	MBT1	MBT0
0x0310	W																
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
[	R	0	FMB6	FMB5	FMB4	FMB3	FMB2	FMB1	FMB0	CRAM		EMBD	PTBF2	DTRE1	PMR	POBF	PIBF
,	W										IVIT IVID	TIMDD	I IDF2	LIDLI	I IVIK	TOBL	TIDE
Reset		0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect on the flag. The register will also be cleared by hard reset or by CHI command CLEAR\_RAMS.

- **PIBF**Parity Error Input Buffer RAM 1,2
  - 1 = Parity error occurred when reading Input Buffer RAM 1,2
  - 0 = No parity error
- **POBF** Parity Error Output Buffer RAM 1,2
  - 1 = Parity error occurred when reading Output Buffer RAM 1,2
  - 0 = No parity error
- PMR Parity Error Message RAM
  - 1 = Parity error occurred when reading the Message RAM
  - 0 = No parity error

#### PTBF1 Parity Error Transient Buffer RAM A

- 1 = Parity error occurred when reading Transient Buffer RAM A
- 0 = No parity error

### PTBF2 Parity Error Transient Buffer RAM B

- 1 = Parity error occurred when reading Transient Buffer RAM B
- 0 = No parity error
- Note: When one of the flags PIBF, POBF, PMR, PTBF1, PTBF2 changes from '0' to '1' EIR.PERR is set to '1'.
- **FMBD** Faulty Message Buffer Detected
  - 1 = Message buffer referenced by **FMB[6:0]** holds faulty data due to a parity error
  - 0 = No faulty message buffer
- **MFMB** Multiple Faulty Message Buffers detected
  - 1 = Another faulty message buffer was detected while flag **FMBD** is set
  - 0 = No additional faulty message buffer
- **CRAM** Clear all internal RAM's

Signals that execution of the CHI command CLEAR\_RAMS is ongoing (all bits of all internal RAM blocks are written to '0'). The bit is set by hard reset or by CHI command CLEAR\_RAMS.

- 1 = Execution of the CHI command CLEAR\_RAMS ongoing
- 0 = No execution of the CHI command CLEAR\_RAMS

**FMB[6:0]** Faulty Message Buffer

Parity error occurred when reading from the message buffer or when transferring data from Input Buffer or Transient Buffer 1,2 to the message buffer referenced by **FMB[6:0]**. Value only valid when one of the flags **PIBF**, **PMR**, **PTBF1**, **PTBF2**, and flag **FMBD** is set. Updated only after the Host has reset flag **FMBD**.

#### MBT[6:0] Message Buffer Transmitted

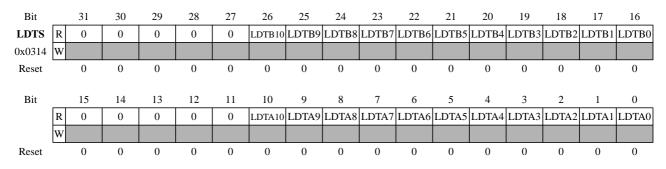

Number of last successfully transmitted message buffer. If the message buffer is configured for single-shot mode, the respective **TXR** flag in the TXRQ1/2/3/4 registers was reset.

#### MBU[6:0] Message Buffer Updated

Number of message buffer that was updated last by the CC. For this message buffer the respective **ND** and / or **MBC** flag in the NDAT1/2/3/4 registers and the MBSC1/2/3/4 registers are also set.

**Note: MBT[6:0]** and **MBU[6:0]** are reset when the CC leaves CONFIG state or enters STARTUP state.

## 4.8.2 Last Dynamic Transmit Slot (LDTS)

The register is reset when the CC leaves CONFIG state or enters STARTUP state.

### **LDTA[10:0]** Last Dynamic Transmission Channel A

Value of vSlotCounter[A] at the time of the last frame transmission on channel A in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

### LDTB[10:0] Last Dynamic Transmission Channel B

Value of vSlotCounter[B] at the time of the last frame transmission on channel B in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FSR	R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
0x0318	W																
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	R	RFFL7	RFFL6	RFFL5	RFFL4	RFFL3	RFFL2	RFFL1	RFFL0	0	0	0	0	0	RFO	RFCL	RFNE
	W																
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### 4.8.3 FIFO Status Register (FSR)

The register is reset when the CC leaves CONFIG state or enters STARTUP state.

#### **RFNE** Receive FIFO Not Empty

This flag is set by the CC when a received valid frame (data or null frame depending on rejection mask) was stored in the FIFO. In addition, interrupt flag **SIR.RFNE** is set. The bit is reset after the Host has read all message from the FIFO.

- 1 = Receive FIFO is not empty
- 0 = Receive FIFO is empty

#### **RFCL** Receive FIFO Critical Level

This flag is set when the receive FIFO fill level **RFFL**[7:0] is equal or greater than the critical level as configured by **FCL.CL**[7:0]. The flag is cleared by the CC as soon as **RFFL**[7:0] drops below **FCL.CL**[7:0]. When **RFCL** changes from '0' to '1' bit **SIR.RFCL** is set to '1', and if enabled, an interrupt is generated.

- 1 = Receive FIFO critical level reached
- 0 = Receive FIFO below critical level

### **RFO** Receive FIFO Overrun

The flag is set by the CC when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, interrupt flag **EIR.RFO** is set. The flag is cleared by the next FIFO read access issued by the Host.

- 1 = A receive FIFO overrun has been detected
- 0 = No receive FIFO overrun detected

#### **RFFL[7:0]** Receive FIFO Fill Level

Number of FIFO buffers filled with new data not yet read by the Host. Maximum value is 128.

#### E-Ray

## 4.8.4 Message Handler Constraints Flags (MHDF)

Some constraints exist for the Message Handler regarding **eray\_bclk** frequency, Message RAM configuration, and FlexRay bus traffic (see Addendum to E-Ray FlexRay IP-Module Specification). To simplify software development, constraints violations are reported by setting flags in the MHDF.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MHDF R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
0x031C W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	WAHP	0	0	TBFB	TBFA	FNFB	ENIEA	CNUD	CNILIA
W								WARP			IDFD	IDГА	ГИГД	FNFA	SNUB	SNUA
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect on the flag. A hard reset will also clear the register. The register is reset when the CC leaves CONFIG state or enters STARTUP state.

SNUA Status Not Updated Channel A

This flag is set by the CC when the Message Handler, due to overload condition, was not able to update a message buffer's status MBS with respect to channel A.

1 = MBS for channel A not updated

0 = No overload condition occurred when updating MBS for channel A

#### **SNUB** Status Not Updated Channel B

This flag is set by the CC when the Message Handler, due to overload condition, was not able to update a message buffer's status MBS with respect to channel B.

- 1 = MBS for channel B not updated
- 0 = No overload condition occurred when updating MBS for channel B

### **FNFA** Find Sequence Not Finished Channel A

This flag is set by the CC when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching message buffer) with respect to channel A.

- 1 = Find sequence not finished for channel A
- 0 = No find sequence not finished for channel A

### **FNFB** Find Sequence Not Finished Channel B

This flag is set by the CC when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching message buffer) with respect to channel B.

- 1 = Find sequence not finished for channel B
- 0 = No find sequence not finished for channel B

### **TBFA** Transient Buffer Access Failure A

This flag is set by the CC when a read or write access to TBF A requested by PRT A could not complete within the available time.

- 1 = TBF A access failure
- 0 = No TBF A access failure

#### **TBFB** Transient Buffer Access Failure B

This flag is set by the CC when a read or write access to TBF B requested by PRT B could not complete within the available time.

- 1 = TBF B access failure
- 0 = No TBF B access failure

#### WAHP Write Attempt to Header Partition

Outside DEFAULT\_CONFIG and CONFIG state this flag is set by the CC when the message handler tries to write message data into the header partition of the Message RAM due to faulty configuration of a message buffer. The write attempt is not executed, to protect the header partition from unintended write accesses.

- 1 = Write attempt to header partition
- 0 = No write attempt to header partition
- Note: When one of the flags SNUA, SNUB, FNFA, FNFB, TBFA, TBFB, WAHP changes from '0' to '1', interrupt flag EIR.MHF is set to '1'.

#### E-Ray

## 4.8.5 Transmission Request 1/2/3/4 (TXRQ1/2/3/4)

The four registers reflect the state of the **TXR** flags of all configured message buffers. The flags are evaluated for transmit buffers only. If the number of configured message buffers is less than 128, the remaining **TXR** flags have no meaning.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### TXR[127:0] Transmission Request

If the flag is set, the respective message buffer is ready for transmission respectively transmission of this message buffer is in progress. In single-shot mode the flags are reset after transmission has completed.

## 4.8.6 New Data 1/2/3/4 (NDAT1/2/3/4)

The four registers reflect the state of the **ND** flags of all configured message buffers. **ND** flags belonging to transmit buffers have no meaning. If the number of configured message buffers is less than 128, the remaining **ND** flags have no meaning. The registers are reset when the CC leaves CONFIG state or enters STARTUP state.

### ND[127:0] New Data

The flags are set when a valid received data frame matches the message buffer's filter configuration, independent of the payload length received or the payload length configured for that message buffer. The flags are not set after reception of null frames except for message buffers belonging to the receive FIFO. An **ND** flag is reset when the header section of the corresponding message buffer is reconfigured or when the data section has been transferred to the Output Buffer.

## 4.8.7 Message Buffer Status Changed 1/2/3/4 (MBSC1/2/3/4)

The four registers reflect the state of the **MBC** flags of all configured message buffers. If the number of configured message buffers is less than 128, the remaining **MBC** flags have no meaning. The registers are reset when the CC leaves CONFIG state or enters STARTUP state.

### MBC[127:0] Message Buffer Status Changed

An MBC flag is set whenever the Message Handler changes one of the status flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB in the header section (see 4.11.5 Message Buffer Status (MBS) and 5.12.1 Header Partition, header 4) of the respective message buffer. An MBC flag is reset when the header section of the corresponding message buffer is reconfigured or when it has been transferred to the Output Buffer.

## 4.9 Identification Registers

## 4.9.1 Core Release Register (CREL)

- **DAY[7:0]** Design Time Stamp, Day Two digits, BCD-coded.
- MON[7:0] Design Time Stamp, Month Two digits, BCD-coded.
- **YEAR[3:0]** Design Time Stamp, Year One digit, BCD-coded.
- **STEP[7:0]** Step of Core Release Two digits, BCD-coded.
- REL[3:0] Core Release One digit, BCD-coded.

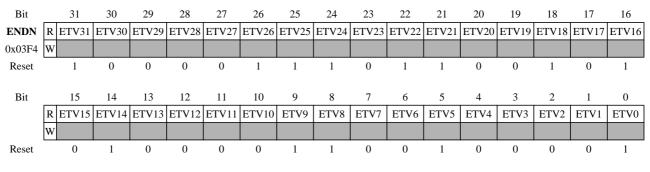

Table 5 below shows how releases are coded in register CREL.

Release	Step	Sub-Step	Name
0	7	0	Beta2
0	7	1	Beta2ct
0	7	2	Revision 1.0RC1
1	0	0	Revision 1.0.0
1	0	1	Revision 1.0.1

nanual\_programmers\_model.fm

 Table 5: Coding for releases

## 4.9.2 Endian Register (ENDN)

## 4.10 Input Buffer

Double buffer structure consisting of Input Buffer Host and Input Buffer Shadow. While the Host can write to Input Buffer Host, the transfer to the Message RAM is done from Input Buffer Shadow. The Input Buffer holds the header and data sections to be transferred to the selected message buffer in the Message RAM. It is used to configure the message buffers in the Message RAM and to update the data sections of transmit buffers.

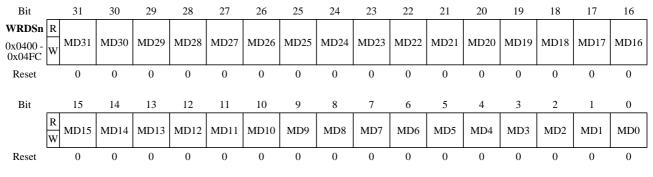

When updating the header section of a message buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in Section 4.11.5 Message Buffer Status (MBS) is automatically reset to zero.

The header sections of message buffers belonging to the receive FIFO can only be (re)configured when the CC is in DEFAULT\_CONFIG or CONFIG state. For those message buffers only the payload length configured and the data pointer need to be configured via **WRHS2.PLC[6.0]** and **WRHS3.DP[10:0]**. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

The data transfer between Input Buffer (IBF) and Message RAM is described in detail in Section 5.11.2.1 Data Transfer from Input Buffer to Message RAM.

### 4.10.1 Write Data Section [1...64] (WRDSn)

Holds the data words to be transferred to the data section of the addressed message buffer. The data words  $(DW_n)$  are written to the Message RAM in transmission order from  $DW_1$  (byte0, byte1) to  $DW_{PL}$  (PL = number of data words as defined by the payload length configured **WRHS2.PLC[6:0]**).

manual\_programmers\_model.fm

MD[31:0] Message Data

 $\begin{array}{ll} \textbf{MD[7:0]} &= DW_n, \ byte_{n-1} \\ \textbf{MD[15:8]} &= DW_n, \ byte_n \end{array}$ 

 $\begin{array}{ll} \textbf{MD[23:16]} &= DW_{n+1}, \text{ byte}_{n+1} \\ \textbf{MD[31:24]} &= DW_{n+1}, \text{ byte}_{n+2} \end{array}$ 

**Note:** DW127 is located on WRDS64.MD[15:0]. In this case WRDS64.MD[31:16] is unused (no valid data). The Input Buffer RAMs are initialized to zero when leaving hard reset or by CHI command CLEAR\_RAMS.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 4.10.2 Write Header Section 1 (WRHS1)

### FID[10:0] Frame ID

Frame ID of the selected message buffer. The frame ID defines the slot number for transmission / reception of the respective message. Message buffers with frame ID = '0' are considered as not valid.

#### CYC[6:0] Cycle Code

The 7-bit cycle code determines the cycle set used for cycle counter filtering. For details about the configuration of the cycle code see Section 5.7.2 Cycle Counter Filtering.

#### CHA, CHB Channel Filter Control

The 2-bit channel filtering field associated with each buffer serves as a filter for receive buffers, and as a control field for transmit buffers.

СНА	СНВ	Transmit Buffer transmit frame on	Receive Buffer store frame received from
1	1	both channels (static segment only)	channel A or B (store first semantically valid frame, static segment only)
1	0	channel A	channel A
0	1	channel B	channel B
0	0	no transmission	ignore frame

**Note:** If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to '1', no frames are transmitted resp. received frames are ignored (same function as **CHA = CHB** = '0')

**CFG** Message Buffer Direction Configuration Bit

This bit is used to configure the corresponding buffer as transmit buffer or as receive buffer. For message buffers belonging to the receive FIFO the bit is not evaluated.

1 = The corresponding buffer is configured as **Transmit Buffer** 

0 = The corresponding buffer is configured as **Receive Buffer** 

PPIT Payload Preamble Indicator Transmit

This bit is used to control the state of the Payload Preamble Indicator in transmit frames. If the bit is set in a static message buffer, the respective message buffer holds network management information. If the bit is set in a dynamic message buffer the first two bytes of the payload segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay frames is not supported by the E-Ray module, but can be done by the Host.

- 1 = Payload Preamble Indicator set
- 0 = Payload Preamble Indicator not set

manual\_programmers\_model.fm

#### TXM Transmission Mode

This bit is used to select the transmission mode (see Section 5.8.3 Transmit Buffers).

- 1 = Single-shot mode
- 0 = Continuous mode

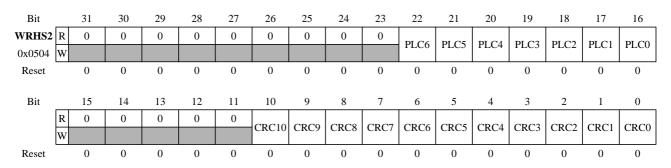

#### MBI Message Buffer Interrupt

This bit enables the receive / transmit interrupt for the corresponding message buffer. After a dedicated receive buffer has been updated by the Message Handler, flag **SIR.RXI** and /or **SIR.MBSI** are set. After a transmission has completed flag **SIR.TXI** is set.

1 = The corresponding message buffer interrupt is enabled

0 = The corresponding message buffer interrupt is disabled

### 4.10.3 Write Header Section 2 (WRHS2)

### CRC[10:0] Header CRC (vRF!Header!HeaderCRC)

Receive Buffer: Configuration not required

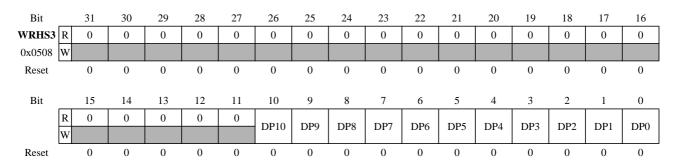

Transmit Buffer: Header CRC calculated and configured by the Host

For calculation of the header CRC the payload length of the frame send on the bus has to be considered. In static segment the payload length of all frames is configured by **MHDC.SFDL[6:0**].

### PLC[6:0] Payload Length Configured

Length of data section (number of 2-byte words) as configured by the Host. During static segment the static frame payload length as configured by **MHDC.SFDL[6:0]** defines the payload length for all static frames. If the payload length configured by **PLC[6:0]** is shorter than this value padding bytes are inserted to ensure that frames have proper physical length. The padding pattern is logical zero.

## 4.10.4 Write Header Section 3 (WRHS3)

#### DP[10:0] Data Pointer

Pointer to the first 32-bit word of the data section of the addressed message buffer in the Message RAM.

## 4.10.5 Input Buffer Command Mask (IBCM)

Configures how the message buffer in the Message RAM selected by register IBCR is updated. When IBF Host and IBF Shadow are swapped, also mask bits **LHSH**, **LDSH**, and **STXRH** are swapped with bits **LHSS**, **LDSS**, and **STXRS** to keep them attached to the respective Input Buffer transfer.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IBCM	R	0	0	0	0	0	0	0	0	0	0	0	0	0	STXRS	LDSS	LHSS
0x0510	W																
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	R	0	0	0	0	0	0	0	0	0	0	0	0	0	STXRH	I DEH	LHSH
	W														SIARH	грэц	споп
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### LHSH Load Header Section Host

- 1 = Header section selected for transfer from Input Buffer to the Message RAM
- 0 = Header section is not updated
- LDSH Load Data Section Host
  - 1 = Data section selected for transfer from Input Buffer to the Message RAM
  - 0 = Data section is not updated

### **STXRH** Set Transmission Request Host

If this bit is set to '1', the **TXR** flag for the selected message buffer is set in the TXRQ1/2/3/4 registers to release the message buffer for transmission. In single-shot mode the flag is cleared by the CC after transmission has completed. **TXR** is evaluated for transmit buffers only.

- 1 = Set **TXR** flag, transmit buffer released for transmission
- $0 = \text{Reset } \mathbf{TXR} \text{ flag}$
- LHSS Load Header Section Shadow
  - 1 = Header section selected for transfer from Input Buffer to the Message RAM (transfer ongoing or finished)
  - 0 = Header section is not updated

### LDSS Load Data Section Shadow

- 1 = Data section selected for transfer from Input Buffer to the Message RAM (transfer ongoing or finished)
- 0 = Data section is not updated

### **STXRS** Set Transmission Request Shadow

- 1 = Set **TXR** flag, transmit buffer released for transmission (operation ongoing or finished)
- $0 = \text{Reset } \mathbf{TXR} \text{ flag}$

## 4.10.6 Input Buffer Command Request (IBCR)

When the Host writes the number of the target message buffer in the Message RAM to **IBRH[6:0]**, IBF Host and IBF Shadow are swapped. In addition the message buffer numbers stored under **IBRH[6:0]** and **IBRS[6:0]** are also swapped (see also Section 5.11.2.1 Data Transfer from Input Buffer to Message RAM).

With this write operation the **IBSYS** is set to '1'. The Message Handler then starts to transfer the contents of IBF Shadow to the message buffer in the Message RAM selected by **IBRS[6:0]**.

While the Message Handler transfers the data from IBF Shadow to the target message buffer in the Message RAM, the Host may write the next message into the IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, **IBSYS** is set back to '0' and the next transfer to the Message RAM may be started by the Host by writing the respective target message buffer number to **IBRH[6:0]**.

If a write access to **IBRH[6:0]** occurs while **IBSYS** is '1', **IBSYH** is set to '1'. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, **IBSYH** is reset to '0'. **IBSYS** remains set to '1', and the next transfer to the Message RAM is started. In addition the message buffer numbers stored under **IBRH[6:0]** and **IBRS[6:0]** are also swapped.

Any write access to an Input Buffer register while both **IBSYS** and **IBSYH** are set will cause the error flag **EIR.IIBA** to be set. In this case the Input Buffer will not be changed.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IBCR	R	IBSYS	0	0	0	0	0	0	0	0	IBRS6	IBRS5	IBRS4	IBRS3	IBRS2	IBRS1	IBRS0
0x0514	W																
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	R	IBSYH	0	0	0	0	0	0	0	0		IDDU5	IDD114	100112	IDDUA	IDDIII	IDDUA
	W										IDKHO	ыкнэ	IBRH4	ыкнэ	IDKH2	IDKHI	IDKH0
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### **IBRH[6:0]** Input Buffer Request Host

Selects the target message buffer in the Message RAM for data transfer from Input Buffer. Valid values are 0x00 to 0x7F (0...127).

### **IBSYH** Input Buffer Busy Host

Set to '1' by writing **IBRH[6:0]** while **IBSYS** is still '1'. After the ongoing transfer between IBF Shadow and the Message RAM has completed, the **IBSYH** is set back to '0'.

1 = Request while transfer between IBF Shadow and Message RAM in progress

0 =No request pending

IBRS[6:0] Input Buffer Request Shadow

Number of the target message buffer actually updated / lately updated. Valid values are 0x00 to 0x7F (0...127).

### **IBSYS** Input Buffer Busy Shadow

Set to '1' after writing **IBRH[6:0]**. When the transfer between IBF Shadow and the Message RAM has completed, **IBSYS** is set back to '0'.

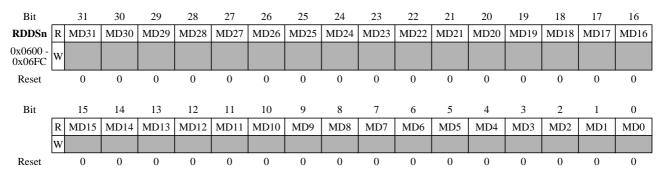

- 1 = Transfer between IBF Shadow and Message RAM in progress
- 0 = Transfer between IBF Shadow and Message RAM completed

## 4.11 Output Buffer

Double buffer structure consisting of Output Buffer Host and Output Buffer Shadow. Used to read out message buffers from the Message RAM. While the Host can read from Output Buffer Host, the Message Handler transfers the selected message buffer from Message RAM to Output Buffer Shadow. The data transfer between Message RAM and Output Buffer (OBF) is described in Section 5.11.2.2 Data Transfer from Message RAM to Output Buffer.

## 4.11.1 Read Data Section [1...64] (RDDSn)

Holds the data words read from the data section of the addressed message buffer. The data words  $(DW_n)$  are read from the Message RAM in reception order from  $DW_1$  (byte0, byte1) to  $DW_{PL}$  (PL = number of data words as defined by the payload length configured **RDHS2.PLC[6:0]**).

MD[31:0] Message Data

- $\begin{array}{ll} \textbf{MD[7:0]} &= DW_n, \ byte_{n-1} \\ \textbf{MD[15:8]} &= DW_n, \ byte_n \\ \textbf{MD[23:16]} &= DW_{n+1}, \ byte_{n+1} \\ \end{array}$
- **MD[31:24]** =  $DW_{n+1}$ , byte<sub>n+2</sub>
- **Note:** DW127 is located on RDDS64.MD[15:0]. In this case RDDS64.MD[31:16] is unused (no valid data). The Output Buffer RAMs are initialized to zero when leaving hard reset or by CHI command CLEAR\_RAMS.

manual\_programmers\_model.fm

#### E-Ray

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### 4.11.2 Read Header Section 1 (RDHS1)

Values as configured by the Host via WRHS1:

FID[10:0] Frame ID

CYC[6:0] Cycle Code

CHA, CHB Channel Filter Control

**CFG** Message Buffer Direction Configuration Bit

**PPIT** Payload Preamble Indicator Transmit

**TXM** Transmission Mode

MBI Message Buffer Interrupt

In case that the message buffer read from the Message RAM belongs to the receive FIFO, **FID**[10:0] holds the received frame ID, while **CYC**[6:0], **CHA**, **CHB**, **CFG**, **PPIT**, **TXM**, and **MBI** are reset to '0'.

#### E-Ray

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### 4.11.3 Read Header Section 2 (RDHS2)

#### **CRC**[10:0] Header CRC (vRF!Header!HeaderCRC)

Receive Buffer: Header CRC updated from received data frames Transmit Buffer: Header CRC calculated and configured by the Host

**PLC[6:0]** Payload Length Configured

Length of data section (number of 2-byte words) as configured by the Host.

#### Payload Length Received (vRF!Header!Length) **PLR**[6:0]

Payload length value updated from received data frames (exception: if message buffer belongs to the receive FIFO PLR[6:0] is also updated from received null frames)

When a message is stored into a message buffer the following behaviour with respect to payload length received and payload length configured is implemented:

<b>PLR[6:0]</b> > <b>PLC[6:0]</b> :	The payload data stored in the message buffer is truncated to the payload length configured if <b>PLC[6:0]</b> even or else truncated to <b>PLC[6:0]</b> + 1.
<b>PLR[6:0]</b> ≤ <b>PLC[6:0]</b> :	The received payload data is stored into the message buffers data section. The remaining data bytes of the data section as configured by <b>PLC[6:0]</b> are filled with undefined data
<b>PLR[6:0]</b> = zero:	The message buffer's data section is filled with undefined data
<b>PLC[6:0]</b> = zero:	Message buffer has no data section configured. No data is stored into the message buffer's data section.

Note: The Message RAM is organized in 4-byte words. When received data is stored into a message buffer's data section, the number of 2-byte data words written into the message buffer is PLC[6:0] rounded to the next even value. PLC[6:0] should be configured identical for all message buffers belonging to the receive FIFO. Header 2 is updated from data frames only.

#### E-Ray

#### 4.11.4 Read Header Section 3 (RDHS3)

#### DP[10:0] Data Pointer

Pointer to the first 32-bit word of the data section of the addressed message buffer in the Message RAM.

#### **RCC**[5:0] Receive Cycle Count (vRF!Header!CycleCount)

Cycle counter value updated from received data frame.

#### **RCI** Received on Channel Indicator (vSS!Channel)

Indicates the channel from which the received data frame was taken to update the respective receive buffer.

- 1 = Frame received on channel A
- 0 = Frame received on channel B

#### Startup Frame Indicator (vRF!Header!SuFIndicator)

A startup frame is marked by the startup frame indicator.

- 1 = The received frame is a startup frame
- 0 = The received frame is not a startup frame

#### **SYN** Sync Frame Indicator (vRF!Header!SyFIndicator)

A sync frame is marked by the sync frame indicator.

- 1 = The received frame is a sync frame
- 0 = The received frame is not a sync frame

#### Null Frame Indicator (vRF!Header!NFIndicator)

#### Is set to '1' after storage of the first received data frame.

- 1 = At least one data frame has been stored into the respective message buffer
- 0 =Up to now no data frame has been stored into the respective message buffer

PPI

nanual\_programmers\_model.fm

SFI

NFI

### Payload Preamble Indicator (vRF!Header!PPIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.

- 1 = Static segment: Network management vector in the first part of the payload Dynamic segment:Message ID in the first part of the payload
- 0 = The payload segment of the received frame does not contain a network management vector nor a message ID

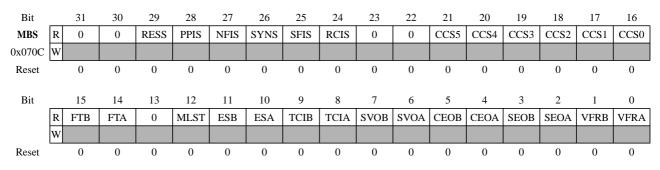

#### **RES** Reserved Bit (vRF!Header!Reserved)

Reflects the state of the received reserved bit. The reserved bit is transmitted as '0'.

#### **Note:** Header 3 is updated from data frames only.

## 4.11.5 Message Buffer Status (MBS)

The message buffer status is updated by the CC with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the message buffer. The flags are updated only when the CC is in NORMAL\_ACTIVE or NORMAL\_PASSIVE state. If only one channel (A or B) is assigned to a message buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a message buffer, the channel-specific status flags of both channels are updated. The message buffer status is updated only when the slot counter reached the configured frame ID and when the cycle counter filter matched. When the Host updates a message buffer via Input Buffer, all MBS flags are reset to zero independent of which IBCM bits are set or not. For details about receive / transmit filtering see Sections 5.7 Filtering and Masking, 5.8 Transmit Process, and 5.9 Receive Process. Whenever the Message Handler changes one of the flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB the respective message buffer's MBC flag in registers MBSC1/2/3/4 is set.

### VFRA Valid Frame Received on Channel A (vSS!ValidFrameA)

A valid frame indication is set if a valid frame was received on channel A.

- 1 = Valid frame received on channel A
- 0 = No valid frame received on channel A

### **VFRB** Valid Frame Received on Channel B (vSS!ValidFrameB)

A valid frame indication is set if a valid frame was received on channel B.

- 1 = Valid frame received on channel B
- 0 = No valid frame received on channel B

### **SEOA** Syntax Error Observed on Channel A (vSS!SyntaxErrorA)

A syntax error was observed in the assigned slot on channel A.

- 1 = Syntax error observed on channel A
- 0 = No syntax error observed on channel A

## **SEOB** Syntax Error Observed on Channel B (vSS!SyntaxErrorB)

A syntax error was observed in the assigned slot on channel B.

- 1 = Syntax error observed on channel B
- 0 = No syntax error observed on channel B

## **CEOA** Content Error Observed on Channel A (vSS!ContentErrorA)

A content error was observed in the assigned slot on channel A.

- 1 = Content error observed on channel A
- 0 = No content error observed on channel A

## **CEOB** Content Error Observed on Channel B (vSS!ContentErrorB)

A content error was observed in the assigned slot on channel B.

- 1 = Content error observed on channel B
- 0 = No content error observed on channel B

- **SVOA** Slot Boundary Violation Observed on Channel A (vSS!BViolationA) A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A.
  - 1 = Slot boundary violation observed on channel A
  - 0 = No slot boundary violation observed on channel A
- **SVOB** Slot Boundary Violation Observed on Channel B (vSS!BViolationB)

A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B.

- 1 = Slot boundary violation observed on channel B
- 0 = No slot boundary violation observed on channel B

#### **TCIA** Transmission Conflict Indication Channel A (vSS!TxConflictA)

A transmission conflict indication is set if a transmission conflict has occurred on channel A.

- 1 = Transmission conflict occurred on channel A
- 0 = No transmission conflict occurred on channel A
- **TCIB** Transmission Conflict Indication Channel B (vSS!TxConflictB)

A transmission conflict indication is set if a transmission conflict has occurred on channel B.

- 1 = Transmission conflict occurred on channel B
- 0 = No transmission conflict occurred on channel B

#### **ESA** Empty Slot Channel A

In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots.

- 1 = No bus activity detected in the assigned slot on channel A
- 0 = Bus activity detected in the assigned slot on channel A
- **ESB** Empty Slot Channel B

In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots.

- 1 = No bus activity detected in the assigned slot on channel B
- 0 = Bus activity detected in the assigned slot on channel B

#### MLST Message Lost

The flag is set in case the Host did not read the message before the message buffer was updated from a received data frame. Not affected by reception of null frames except for message buffers belonging to the receive FIFO. The flag is reset by a Host write to the message buffer via IBF or when a new message is stored into the message buffer **after** the message buffers **ND** flag was reset by reading out the message buffer via OBF.

- 1 = Unprocessed message was overwritten
- 0 = No message lost

### **FTA** Frame Transmitted on Channel A

Indicates that this node has transmitted a data frame in the configured slot on channel A.

- 1 = Data frame transmitted on channel A
- 0 = No data frame transmitted on channel A

### **FTB** Frame Transmitted on Channel B

Indicates that this node has transmitted a data frame in the configured slot on channel B.

- 1 = Data frame transmitted on channel B
- 0 = No data frame transmitted on channel B

**Note:** The FlexRay protocol specification requires that **FTA**, and **FTB** can only be reset by the Host. Therefore the Cycle Count Status **CCS**[5:0] for these bits is only valid for the cycle where the bits are set to '1'.

CCS[5:0] Cycle Count Status Actual cycle count when status was updated.

For receive buffers (CFG = '0') the following status bits are updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.

**RCIS** Received on Channel Indicator Status (vSS!Channel)

Indicates the channel on which the frame was received.

- 1 = Frame received on channel A
- 0 = Frame received on channel B
- SFIS Startup Frame Indicator Status (vRF!Header!SuFIndicator)

A startup frame is marked by the startup frame indicator.

- 1 = The received frame is a startup frame
- 0 = No startup frame received

**SYNS** Sync Frame Indicator Status (vRF!Header!SyFIndicator)

A sync frame is marked by the sync frame indicator.

- 1 = The received frame is a sync frame
- 0 = No sync frame received
- **NFIS** Null Frame Indicator Status (vRF!Header!NFIndicator)

If set to '0' the payload segment of the received frame contains no usable data.

- 1 = Received frame is **not** a null frame
- 0 = Received frame is a null frame

**PPIS** Payload Preamble Indicator Status (vRF!Header!PPIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.

- 1 = Static segment: Network management vector at the beginning of the payload Dynamic segment: Message ID at the beginning of the payload
- 0 = The payload segment of the received frame does not contain a network management vector or a message ID

### **RESS** Reserved Bit Status (vRF!Header!Reserved)

Reflects the state of the received reserved bit. The reserved bit is transmitted as '0'.

## 4.11.6 Output Buffer Command Mask (OBCM)

Configures how the Output Buffer is updated from the message buffer in the Message RAM selected by register OBCR. When OBF Host and OBF Shadow are swapped, also mask bits **RDSH** and **RHSH** are swapped with bits **RDSS** and **RHSS** to keep them attached to the respective Output Buffer transfer.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OBCM R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	RDSH	RHSH
0x0710 W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W															KD35	кпээ
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### **RHSS** Read Header Section Shadow

- 1 = Header section selected for transfer from Message RAM to Output Buffer
- 0 = Header section is not read
- **RDSS** Read Data Section Shadow
  - 1 = Data section selected for transfer from Message RAM to Output Buffer
  - 0 = Data section is not read
- **RHSH** Read Header Section Host
  - 1 = Header section selected for transfer from Message RAM to Output Buffer
  - 0 = Header section is not read

### **RDSH** Read Data Section Host

- 1 = Data section selected for transfer from Message RAM to Output Buffer
- 0 = Data section is not read
- **Note:** After the transfer of the header section from the Message RAM to OBF Shadow has completed, the message buffer status changed flag **MBC** of the selected message buffer in the MBSC1/2/3/4 registers is cleared. After the transfer of the data section from the Message RAM to OBF Shadow has completed, the new data flag **ND** of the selected message buffer in the NDAT1/2/3/4 registers is cleared.

## 4.11.7 Output Buffer Command Request (OBCR)

The message buffer selected by **OBRS**[6:0] is transferred from the Message RAM to the Output Buffer as soon as the Host has set **REQ** to '1'. Bit **REQ** can only be set to '1' while **OBSYS** is '0' (see also Section 5.11.2.2 Data Transfer from Message RAM to Output Buffer).

After setting **REQ** to '1', **OBSYS** is automatically set to '1', and the transfer of the message buffer selected by **OBRS[6:0]** from the Message RAM to OBF Shadow is started. When the transfer between the Message RAM and OBF Shadow has completed, this is signalled by setting **OBSYS** back to '0'. By setting the **VIEW** bit to '1' while **OBSYS** is '0', OBF Host and OBF Shadow are swapped. Now the Host can read the transferred message buffer from OBF Host. In parallel the Message Handler may transfer the next message from the Message RAM to OBF Shadow if **VIEW** and **REQ** are set at the same time.

Any write access to an Output Buffer register while **OBSYS** is set will cause the error flag **EIR.IOBA** to be set. In this case the Output Buffer will not be changed.

Bit		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OBCR	R	0	0	0	0	0	0	0	0	0	OBRH6	OBRH5	OBRH4	OBRH3	OBRH2	OBRH1	OBRH0
0x0714	W																
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	R	OBSYS	0	0	0	0	0	REQ	VIEW	0	OBBS6	OBDS5	OBDSA	OBD23	OBDSJ	OBDS1	OBRS0
	W							KĽŲ	VIL W		OBR30	OBR35	UDK34	ODK35	ODK32	ODK31	OBRSU
Reset		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### **OBRS[6:0]** Output Buffer Request Shadow

Number of source message buffer to be transferred from the Message RAM to OBF Shadow. Valid values are 0x00 to 0x7F (0...127). If the number of the first message buffer of the receive FIFO is written to this register the Message Handler transfers the message buffer addressed by the GET Index (GIDX, see Section 5.10 FIFO Function) to OBF Shadow.

#### **VIEW** View Shadow Buffer

Toggles between OBF Shadow and OBF Host. Only writeable while **OBSYS** = '0'.

1 = Swap OBF Shadow and OBF Host

0 = No action

## **REQ** Request Message RAM Transfer

Requests transfer of message buffer addressed by **OBRS**[6:0] from Message RAM to OBF Shadow. Only writeable while **OBSYS** = '0'.

- 1 = Transfer to OBF Shadow requested
- 0 = No request

### **OBSYS** Output Buffer Busy Shadow

Set to '1' after setting bit **REQ**. When the transfer between the Message RAM and OBF Shadow has completed, **OBSYS** is set back to '0'.

- 1 = Transfer between Message RAM and OBF Shadow in progress
- 0 = No transfer in progress

### **OBRH[6:0]** Output Buffer Request Host

Number of message buffer currently accessible by the Host via RDHS[1...3], MBS, and RDDS[1...64]. By writing **VIEW** to '1' OBF Shadow and OBF Host are swapped and the transferred message buffer is accessible by the Host. Valid values are 0x00 to 0x7F (0...127).

## 5. Functional Description

This chapter describes the E-Ray implementation together with the related FlexRay protocol features. More information about the FlexRay protocol itself can be found in the FlexRay protocol specification v2.1.

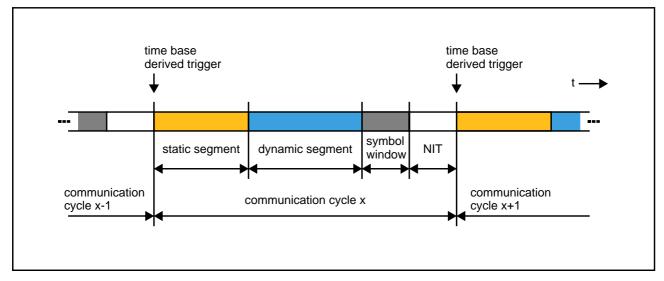

Communication on FlexRay networks is based on frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to setup the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

## 5.1 Communication Cycle

A FlexRay communication cycle consists of the following elements:

- Static Segment
- Dynamic Segment (optional)
- Symbol Window (optional)
- Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized macrotick.

manual\_functional\_description.fm

Figure 2: Structure of communication cycle

## 5.1.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of frame transmission at action point of the respective static slot
- Payload length same for all frames on both channels

### Parameters: Number of Static Slots GTUC7.NSS[9:0], Static Slot Length GTUC7.SSL[9:0], Payload Length Static MHDC.SFDL[6:0], Action Point Offset GTUC9.APO[5:0]

## 5.1.2 Dynamic Segment

E-Ray

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters: Number of Minislots GTUC8.NMS[12:0], Minislot Length GTUC8.MSL[5:0], Minislot Action Point Offset GTUC9.MAPO[4:0], Start of Latest Transmit (last minislot) MHDC.SLT[12:0]

## 5.1.3 Symbol Window

During the symbol window only **one** media access test symbol (MTS) may be transmitted per channel. MTS symbols are send in NORMAL\_ACTIVE state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Parameters: Symbol Window Action Point Offset GTUC9.APO[4:0] (same as for static slots), Network Idle Time Start GTUC4.NIT[13:0]

### 5.1.4 Network Idle Time (NIT)

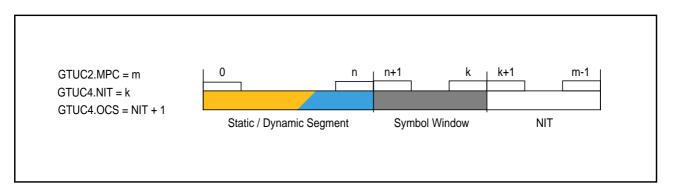

During network idle time the CC has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple macroticks after offset correction start
- Perform cluster cycle related tasks

Parameters: Network Idle Time Start GTUC4.NIT[13:0], Offset Correction Start GTUC4.OCS[13:0]

#### E-Ray

## 5.1.5 Configuration of NIT Start and Offset Correction Start

#### Figure 3: Configuration of NIT start and offset correction start

The number of macroticks per cycle gMacroPerCycle is assumed to be m. It is configured by programming **GTUC2.MPC** = m.

The static / dynamic segment starts with macrotick 0 and ends with macrotick n: n = static segment length + dynamic segment offset + dynamic segment length - 1MT n = gNumberOfStaticSlots • gdStaticSlot + dynamic segment offset + gNumberOfMinislots • gdMinislot - 1 MT

The static segment length is configured by **GTUC7.SSL** and **GTUC7.NSS**. The dynamic segment length is configured by **GTUC8.MSL** and **GTUC8.NMS**.

The dynamic segment offset is: If gdActionPointOffset ≤ gdMinislotActionPointOffset: dynamic segment offset = 0 MT Else if gdActionPointOffset > gdMinislotActionPointOffset: dynamic segment offset = gdActionPointOffset - gdMinislotActionPointOffset

The NIT starts with macrotick k+1 and ends with the last macrotick of cycle m-1. It has to be configured by setting **GTUC4.NIT** = k.

For the E-Ray the offset correction start is required to be **GTUC4.OCS**  $\ge$  **GTUC4.NIT** + 1 = k+1.

The length of symbol window results from the number of macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by k - n.

## **5.2 Communication Modes**

The FlexRay Protocol Specification v2.1 defines the Time-Triggered Distributed (TT-D) mode.

## 5.2.1 Time-triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- **Pure static**: Minimum 2 static slots + symbol window (optional)
- **Mixed static/dynamic**: Minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes needs to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each startup frame must be a sync frame, therefore all coldstart nodes are sync nodes.

## 5.3 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received sync frames from other nodes.

## 5.3.1 Global Time

E-Ray

Activities in a FlexRay node, including communication, are based on the concept of a global time, even though each individual node maintains its own view of it. It is the clock synchronization mechanism that differentiates the FlexRay cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (macrotick counter).

#### **Cluster specific:**

- Macrotick (MT) = basic unit of time measurement in a FlexRay network, a macrotick consists of an integer number of microticks ( $\mu$ T)
- Cycle length = duration of a communication cycle in units of macroticks (MT)

### 5.3.2 Local Time

Internally, nodes time their behaviour with microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a microtick ( $\mu$ T).

#### Node specific:

- Oscillator clock -> prescaler -> microtick ( $\mu$ T)
- $\mu$ T = basic unit of time measurement in a CC, clock correction is done in units of  $\mu$ Ts
- Cycle counter + macrotick counter = nodes local view of the global time

### **5.3.3 Synchronization Process**

Clock synchronization is performed by means of sync frames. Only preconfigured nodes (sync nodes) are allowed to send sync frames. In a two-channel cluster a sync node has to send its sync frame on both channels.

For synchronization in FlexRay the following constraints have to be considered:

- Max. one sync frame per node in one communication cycle
- Max. 15 sync frames per cluster in one communication cycle
- Every node has to use a preconfigured number of sync frames (GTUC2.SNM[3:0]) for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of sync frames received during the static segment is measured. In a two channel cluster the sync node has to be configured to send sync frames on both channels. The calculation of correction terms is done during NIT (offset: every cycle, rate: every odd cycle) by using an FTM algorithm. For details see FlexRay protocol specification v2.1, chapter 8.

BOSCH

## 5.3.3.1 Offset (phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during NIT of every communication cycle
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values

E-Ray

- Correction value is a signed integer number of  $\mu Ts$
- Correction done in **odd** numbered cycles, distributed over the macroticks beginning at offset correction start up to cycle end (end of NIT) to shift nodes next start of cycle (MTs lengthened / shortened)

## 5.3.3.2 Rate (frequency) Correction

- Pairs of deviation values measured and stored in even / odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during NIT of odd numbered cycles
- Cluster drift damping is performed using global damping value
- Checked against limit values
- Correction value is a signed integer number of  $\mu Ts$
- Distributed over macroticks comprising the next **even / odd** cycle pair (MTs lengthened / shortened)

## 5.3.3.3 Sync Frame Transmission

Sync frame transmission is only possible from buffer 0 and 1. Message buffer 1 may be used for sync frame transmission in case that sync frames should have different payloads on the two channels. In this case bit **MRC.SPLM** has to be programmed to '1'.

Message buffers used for sync frame transmission have to be configured with the key slot ID and can be (re)configured in DEFAULT\_CONFIG or CONFIG state only. For nodes transmitting sync frames **SUCC1.TXSY** must be set to '1'.

## 5.3.4 External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset / rate correction value is a signed integer
- External offset / rate correction value is added to calculated offset / rate correction value
- Aggregated offset / rate correction term (external + internal) is not checked against configured limits

## 5.4 Error Handling

E-Ray

The implemented error handling concept is intended to ensure that, in case of a lower layer protocol error in one single node, communication between non-affected nodes can be maintained. In some cases, higher layer program activity is required for the CC to resume normal operation. A change of the error handling state will set **EIR.PEMC** and may trigger an interrupt to the Host if enabled. The actual error mode is signalled by **CCEV.ERRM[1:0]**.

Error Mode	Activity
ACTIVE (green)	<b>Full operation</b> , State: NORMAL_ACTIVE The CC is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers EIR and SIR.
PASSIVE (yellow)	<b>Reduced operation</b> , State: NORMAL_PASSIVE, CC self rescue allowed The CC stops transmitting frames and symbols, but received frames are still processed. Clock synchronization mechanisms are continued based on received frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers EIR and SIR.
COMM_HALT (red)	<b>Operation halted</b> , State: HALT, CC self rescue not allowed The CC stops frame and symbol processing, clock synchronization processing, and the macrotick generation. The host has still access to error and status information by read- ing the error and status interrupt flags from registers EIR and SIR. The bus drivers are disabled.

 Table 6: Error modes of the POC (degradation model)

### 5.4.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the "maximum without clock correction passive" limit defined by **SUCC3.WCP[3:0]**, the POC transits from NORMAL\_ACTIVE to NORMAL\_PASSIVE state. When it reaches the "maximum without clock correction fatal" limit defined by **SUCC3.WCF[3:0]**, it transits from NORMAL\_ACTIVE or NORMAL\_PASSIVE to HALT state.

The Clock Correction Failed Counter **CCEV.CCFC**[3:0] allows the Host to monitor the duration of the inability of a node to compute clock correction terms after the CC passed protocol startup phase. It will be incremented by one at the end of any **odd** communication cycle during which either the missing offset correction **SFS.MOCS** or the missing rate correction **SFS.MRCS** flag is set.

The Clock Correction Failed Counter is reset to zero at the end of an **odd** communication cycle if neither the missing offset correction **SFS.MOCS** nor the missing rate correction **SFS.MRCS** flag is set.

The Clock Correction Failed Counter stops incrementing when the "maximum without clock correction fatal" value **SUCC3.WCF[3:0]** is reached (i.e. incrementing the counter at its maximum value will not cause it to wrap around back to zero). The Clock Correction Failed Counter is initialized to zero when the CC enters READY state or when NORMAL\_ACTIVE state is entered.

#### 5.4.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from NORMAL\_PASSIVE to NORMAL\_ACTIVE state. **SUCC1.PTA[4:0]** defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL\_PASSIVE to NORMAL\_ACTIVE state. If **SUCC1.PTA[4:0]** is set to zero the CC is not allowed to transit from NORMAL\_PASSIVE to NORMAL\_PAS

### 5.4.3 HALT Command

In case the Host wants to stop FlexRay communication of the local node it can bring the CC into HALT state by asserting the HALT command. This can be done by writing **SUCC1.CMD[3:0]** = "0110". In order to shut down communication on an entire FlexRay network, a higher layer protocol is required to assure that all nodes apply the HALT command at the same time.

The POC state from which the transition to HALT state took place can be read from CCSV.PSL[5:0].

When called in NORMAL\_ACTIVE or NORMAL\_PASSIVE state the POC transits to HALT state at the end of the current cycle. When called in any other state **SUCC1.CMD[3:0]** will be reset to "0000" = command\_not\_accepted and bit **EIR.CNA** is set to '1'. If enabled an interrupt to the Host is generated.

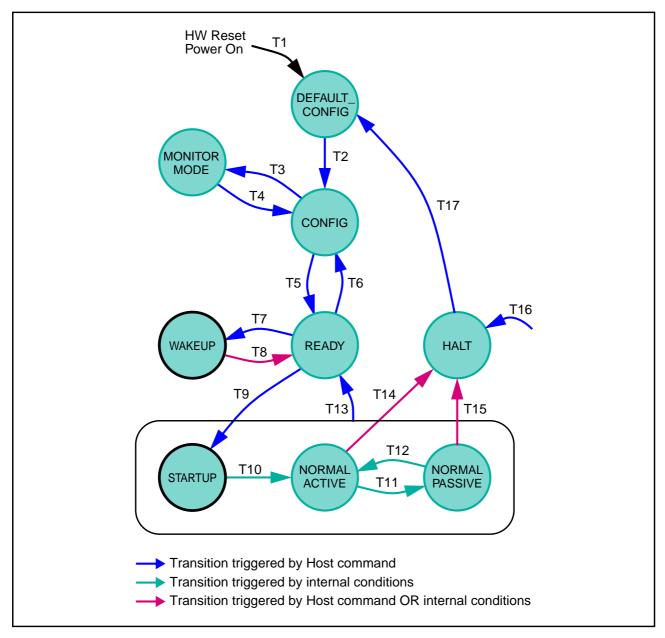

### 5.4.4 FREEZE Command

In case the Host detects a severe error condition it can bring the CC into HALT state by asserting the FREEZE command. This can be done by writing **SUCC1.CMD[3:0]** = "0111". The FREEZE command triggers the entry of the HALT state immediately regardless of the actual POC state.

The POC state from which the transition to HALT state took place can be read from CCSV.PSL[5:0].

## **5.5 Communication Controller States**

## 5.5.1 Communication Controller State Diagram

manual\_functional\_description.fm

Figure 4: Overall state diagram of E-Ray communication controller

State transitions are controlled by externals pins **eray\_reset** and **eray\_rxd1,2**, by the POC state machine, and by the CHI Command Vector **SUCC1.CMD[3:0]**.

The CC exits from **all** states to HALT state after application of the FREEZE command (**SUCC1.CMD[3:0]** = "0111").

T#	Condition	From	То
1	Hard reset	All States	DEFAULT_CONFIG
2	Command CONFIG, SUCC1.CMD[3:0] = "0001"	DEFAULT_CONFIG	CONFIG
3	Unlock sequence followed by command MONITOR_MODE, <b>SUCC1.CMD[3:0]</b> = "1011"	CONFIG	MONITOR_MODE
4	Command CONFIG, SUCC1.CMD[3:0] = "0001"	MONITOR_MODE	CONFIG
5	Unlock sequence followed by command READY, SUCC1.CMD[3:0] = "0010"	CONFIG	READY
6	Command CONFIG, SUCC1.CMD[3:0] = "0001"	READY	CONFIG
7	Command WAKEUP, SUCC1.CMD[3:0] = "0011"	READY	WAKEUP
8	Complete, non-aborted transmission of wakeup pat- tern OR received WUP OR received frame header OR wakeup collision OR command READY, <b>SUCC1.CMD[3:0]</b> = "0010"	WAKEUP	READY
9	Command RUN, <b>SUCC1.CMD[3:0]</b> = "0100"	READY	STARTUP
10	Successful startup	STARTUP	NORMAL_ACTIVE
11	Clock Correction Failed counter reached Maximum Without Clock Correction Passive limit configured by SUCC3.WCP[3:0]	NORMAL_ACTIVE	NORMAL_PASSIVE
12	Number of valid correction terms reached the Passive to Active limit configured by <b>SUCC1.PTA[4:0]</b>	NORMAL_PASSIVE	NORMAL_ACTIVE
13	Command READY, SUCC1.CMD[3:0] = "0010"	STARTUP, NORMAL_ACTIVE, NORMAL_PASSIVE	READY
14	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by <b>SUCC3.WCF[3:0]</b> AND bit <b>SUCC1.HCSE</b> set to '1' OR command HALT, <b>SUCC1.CMD[3:0]</b> = "0110"	NORMAL_ACTIVE	HALT
15	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by <b>SUCC3.WCF[3:0]</b> AND bit <b>SUCC1.HCSE</b> set to '1' OR command HALT, <b>SUCC1.CMD[3:0]</b> = "0110"	NORMAL_PASSIVE	HALT
16	Command FREEZE, SUCC1.CMD[3:0] = "0111"	All States	HALT
17	Command CONFIG, SUCC1.CMD[3:0] = "0001"	HALT	DEFAULT_CONFIG

Table 7: State transitions of E-Ray overall state machine

# 5.5.2 DEFAULT\_CONFIG State

In DEFAULT\_CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The CC enters this state

E-Ray

- When leaving hard reset (external reset signal **eray\_reset** is deactivated)
- When exiting from HALT state

To leave DEFAULT\_CONFIG state the Host has to write **SUCC1.CMD[3:0]** = "0001". The CC then transits to CONFIG state.

## 5.5.3 CONFIG State

In CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the CC configuration.

The CC enters this state

- When exiting from DEFAULT\_CONFIG state
- When exiting from MONITOR\_MODE or READY state

When the state has been entered via HALT and DEFAULT\_CONFIG state, the Host can analyse status information and configuration. Before leaving CONFIG state the Host has to assure that the configuration is fault-free.

To leave CONFIG state, the Host has to perform the unlock sequence as described in 4.3.1 Lock Register (LCK). Directly after unlocking the CONFIG state the Host has to write **SUCC1.CMD[3:0]** to enter the next state.

Internal counters and the CC status flags are reset when the CC leaves CONFIG state.

**Note:** Status bits MHDS[14:0], registers TXRQ1/2/3/4, and status data stored in the Message RAM are not affected by the transition of the POC from CONFIG to READY state.

When the CC is in CONFIG state it is also possible to bring the CC into a power saving mode by halting the module clocks (**eray\_sclk**, **eray\_bclk**). To do this the Host has to assure that all Message RAM transfers have finished before turning off the clocks.

# 5.5.4 MONITOR\_MODE

After unlocking CONFIG state and writing **SUCC1.CMD[3:0]** = "1011" the CC enters MONITOR\_MODE. In this mode the CC is able to receive FlexRay frames and to detect wakeup pattern. The temporal integrity of received frames is not checked, and therefore cycle counter filtering is not supported. This mode can be used for debugging purposes in case e.g. that startup of a FlexRay network fails. After writing **SUCC1.CMD[3:0]** = "0001" the CC transits back to CONFIG state.

In MONITOR\_MODE the pick first valid mechanism is disabled. This means that a receive message buffer may only be configured to receive on one channel. Received frames are stored into message buffers according to frame ID and receive channel. Null frames are handled like data frames. After frame reception only status bits **MBS.VFRA**, **MBS.VFRB**, **MBS.MLST**, **MBS.RCIS**, **MBS.SFIS**, **MBS.SYNS**, **MBS.NFIS**, **MBS.PPIS**, **MBS.RESS** have valid values.

In MONITOR\_MODE the CC is not able to distinguish between CAS and MTS symbols. In case one of these symbols is received on one or both of the two channels, the flags **SIR.MTSA** resp. **SIR.MTSB** are set. **SIR.CAS** has no function in MONITOR\_MODE.

# 5.5.5 READY State

After unlocking CONFIG state and writing **SUCC1.CMD[3:0]** = "0010" the CC enters READY state. From this state the CC can transit to WAKEUP state and perform a cluster wakeup or to STARTUP state to perform a coldstart or to integrate into a running cluster.

The CC enters this state

• When exiting from CONFIG, WAKEUP, STARTUP, NORMAL\_ACTIVE, or NORMAL\_PASSIVE state by writing **SUCC1.CMD[3:0]** = "0010" (READY command).

The CC exits from this state

- To CONFIG state by writing **SUCC1.CMD[3:0]** = "0001" (CONFIG command)
- To WAKEUP state by writing **SUCC1.CMD[3:0]** = "0011" (WAKEUP command)
- To STARTUP state by writing **SUCC1.CMD[3:0]** = "0100" (RUN command)

Internal counters and the CC status flags are reset when the CC enters STARTUP state.

**Note:** Status bits MHDS[14:0], registers TXRQ1/2/3/4, and status data stored in the Message RAM are not affected by the transition of the POC from READY to STARTUP state.

# 5.5.6 WAKEUP State

E-Ray

The description below is intended to help configuring wakeup for the E-Ray IP-module. A detailed description of the wakeup procedure together with the respective SDL diagrams can be found in the FlexRay protocol specification v2.1, section 7.1.

The CC enters this state

• When exiting from READY state by writing **SUCC1.CMD[3:0]** = "0011" (WAKEUP command).

The CC exits from this state to READY state

- After complete non-aborted transmission of wakeup pattern
- After WUP reception
- After detecting a WUP collision
- After reception of a frame header
- By writing **SUCC1.CMD[3:0]** = "0010" (READY command)

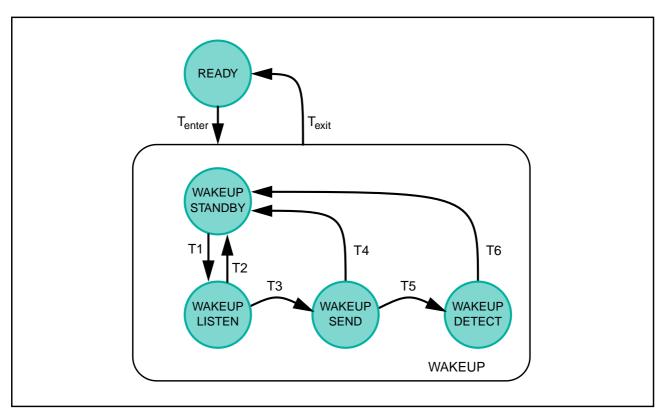

The cluster wakeup must precede the communication startup in order to ensure that all nodes in a cluster are awake. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an **external** wakeup source.

The Host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the CC and configures bus guardian (if available) and CC to perform the cluster wakeup. The CC provides to the Host the ability to transmit a special wakeup pattern on each of its available channels separately. The CC needs to recognize the wakeup pattern only during WAKEUP state.

Wakeup may be performed on only one channel at a time. The Host has to configure the wakeup channel while the CC is in CONFIG state by writing **SUCC1.WUCS**. The CC ensures that ongoing communication on this channel is not disturbed. The CC cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the CC returns to READY state and signals the change of the wakeup status to the Host by setting flag **SIR.WST**. The wakeup status vector can be read from **CCSV.WSV[2:0]**. If a valid wakeup pattern was received also either flag **SIR.WUPA** or flag **SIR.WUPB** is set.

### Figure 5: Structure of POC state WAKEUP

T#	Condition	From	То
enter	Host commands change to WAKEUP state by writ- ing <b>SUCC1.CMD[3:0]</b> = "0011" (WAKEUP com- mand)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to WAKEUP_LISTEN state	WAKEUP_STANDBY	WAKEUP_LISTEN
2	Received WUP on wakeup channel selected by bit <b>SUCC1.WUCS</b> OR frame header on either available channel	WAKEUP_LISTEN	WAKEUP_STANDBY
3	Timer event	WAKEUP_LISTEN	WAKEUP_SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_SEND	WAKEUP_STANDBY
5	Collision detected	WAKEUP_SEND	WAKEUP_DETECT
6	Wakeup timer expired OR WUP detected on wakeup channel selected by bit <b>SUCC1.WUCS</b> OR frame header received on either available channel	WAKEUP_DETECT	WAKEUP_STANDBY
exit	Wakeup completed (after T2 or T4 or T6) OR Host commands change to READY state by writing <b>SUCC1.CMD[3:0]</b> = "0010" (READY command). This command also resets the wakeup FSM to WAKEUP_STANDBY state	WAKEUP	READY

Table 8: State transitions WAKEUP

The WAKEUP\_LISTEN state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters listen timeout **SUCC2.LT[20:0]** and listen timeout noise **SUCC2.LTN[3:0]**. Listen timeout enables a fast cluster wakeup in case of a noise free environment, while listen timeout noise enables wakeup under more difficult conditions regarding noise interference.

In WAKEUP\_SEND state the CC transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the Host has to bring the CC into STARTUP state by CHI command RUN.

In WAKEUP\_DETECT state the CC attempts to identify the reason for the wakeup collision detected in WAKEUP\_SEND state. The monitoring is bounded by the expiration of listen timeout as configured by **SUCC2.LT[20:0]**. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a frame header indicating ongoing communication, causes the direct transition to READY state. Otherwise WAKEUP\_DETECT is left after expiration of listen timeout; in this case the reason for wakeup collision is unknown.

The Host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay Protocol Specification v2.1 recommends that two different CCs shall awake the two channels.

# 5.5.6.1 Host activities

The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the Host. The wakeup pattern is detected by the remote BDs and signalled to their local Host.

# Wakeup procedure controlled by Host (single-channel wakeup):

- Configure the CC in CONFIG state
- Select wakeup channel by programming bit SUCC1.WUCS
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command CC to enter READY state
- Command CC to start wakeup on the configured channel by writing **SUCC1.CMD[3:0]** = "0011"
- CC enters WAKEUP
- CC returns to READY state and signals status of wakeup attempt to the Host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node:
- In a dual channel cluster wait for WUP on the other channel
- Reset coldstart inhibit flag **CCSV.CSI** by writing **SUCC1.CMD[3:0]** = "1001" (ALLOW\_COLDSTART command)
- Command CC to enter startup by writing **SUCC1.CMD[3:0]** = "0100" (RUN command)

# E-Ray

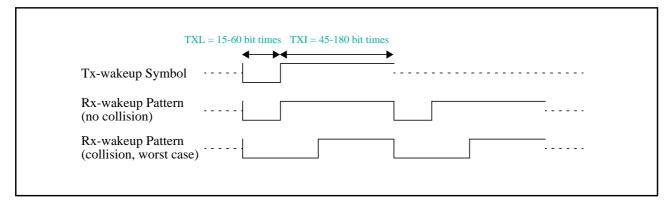

# Wakeup procedure triggered by BD:

- Wakeup recognized by BD
- BD triggers power-up of Host (if required)
- BD signals wakeup event to Host
- Host configures its local CC
- If necessary, Host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands CC to enter STARTUP state by writing **SUCC1.CMD[3:0]** = "0100" (RUN command)

# 5.5.6.2 Wakeup pattern (WUP)

The wakeup pattern (WUP) is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by registers PRTC1 and PRTC2.

- Single channel wakeup, wakeup symbol may not be sent on both channels at the same time
- Wakeup symbol collision resilient for at least two sending nodes (two overlapping wakeup symbols always recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by **PRTC2.TXL**[5:0]
- Wakeup symbol idle time used to listen for activity on the bus, configured by **PRTC2.TXI**[7:0]
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by **PRTC1.RWP[5:0]** (2 to 63 repetitions)
- Wakeup symbol receive window length configured by **PRTC1.RXW[8:0]**
- Wakeup symbol receive low time configured by **PRTC2.RXL**[5:0]
- Wakeup symbol receive idle time configured by **PRTC2.RXI**[5:0]

manual\_functional\_description.fm

# E-Ray

# 5.5.7 STARTUP State

The description below is intended to help configuring startup for the E-Ray IP-module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the FlexRay protocol specification v2.1, section 7.2.

Any node entering STARTUP state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup frames. Startup frames are both sync frames and null frames during startup.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter NORMAL\_ACTIVE state via (see Figure 7):

- Coldstart path initiating the schedule synchronization (leading coldstart node)
- Coldstart path joining other coldstart nodes (following coldstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has bits **SUCC1.TXST** and **SUCC1.TXSY** set to '1'. Message buffer 0 holds the key slot ID which defines the slot number where the startup frame is send. In the frame header of the startup frame the startup frame indicator bit is set.

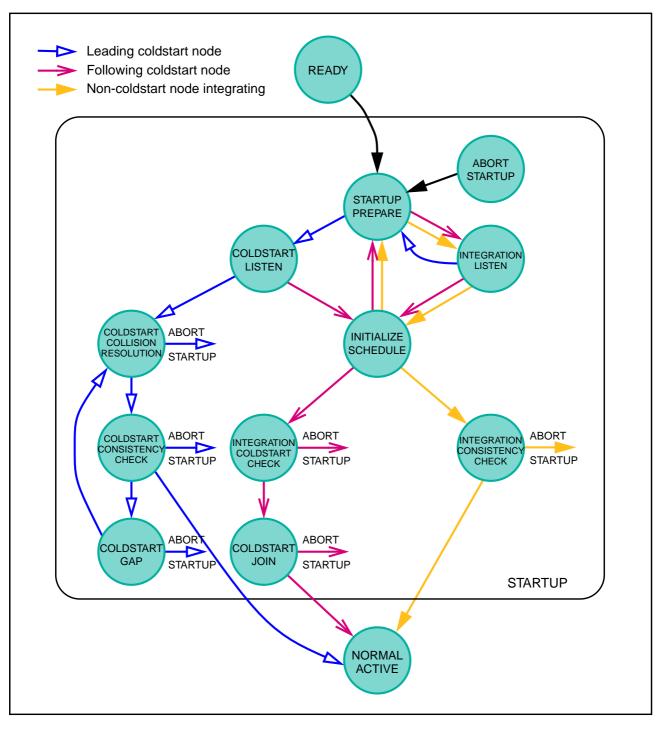

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each startup frame must also be a sync frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by **SUCC1.CSA[4:0]**.

A non-coldstart node requires at least two startup frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration via the integration path as soon as they receive sync frames from which to derive the TDMA schedule information. During integration, the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

BOSCH

manual\_functional\_description.fm

Figure 7: State diagram time-triggered startup

# 5.5.7.1 Coldstart Inhibit Mode

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit **CCSV.CSI** is set, the node is not allowed to initialize the cluster communication, i.e. entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit **CCSV.CSI** is set whenever the POC enters READY state. The bit has to be cleared under control of the Host by CHI command ALLOW\_COLDSTART (**SUCC1.CMD[3:0]** = "1001")

# 5.5.7.2 Startup Timeouts

The CC supplies two different  $\mu$ T timers supporting two timeout values, startup timeout and startup noise timeout. The two timers are started when the CC enters the COLDSTART\_LISTEN state. The expiration of either of these timers causes the node to leave the initial sensing phase (COLDSTART\_LISTEN state) with the intention of starting up communication.

**Note:** The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values **SUCC2.LT[20:0]** and **SUCC2.LTN[3:0]**.

# **Startup Timeout**

The startup timeout limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others. The startup timer is configured by programming **SUCC2.LT[20:0]** (see 4.5.2 SUC Configuration Register 2 (SUCC2)).

The startup timeout is: pdListenTimeout = SUCC2.LT[20:0]

The startup timer is restarted upon:

- Entering the COLDSTART\_LISTEN state
- Both channels reaching idle state while in COLDSTART\_LISTEN state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the COLDSTART\_LISTEN state
- When the COLDSTART\_LISTEN state is left

Once the startup timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

# **Startup Noise Timeout**

At the same time the startup timer is started for the first time (transition from STARTUP\_PREPARE state to COLDSTART\_LISTEN state), the startup noise timer is started. This additional timeout is used to improve reliability of the startup procedure in the presence of noise. The startup noise timeout is configured by programming **SUCC2.LTN[3:0]** (see 4.5.2 SUC Configuration Register 2 (SUCC2)).

The startup noise timeout is: pdListenTimeout • gListenNoise = SUCC2.LT[20:0] • (SUCC2.LTN[3:0] + 1)

The startup noise timer is restarted upon:

- Entering the COLDSTART\_LISTEN state
- Reception of correctly decoded headers or CAS symbols while the node is in COLDSTART\_LISTEN state

The startup noise timer is stopped when the COLDSTART\_LISTEN state is left.

Once the startup noise timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won't be restarted when random channel activity is sensed, this timeout defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

# 5.5.7.3 Path of leading Coldstart Node (initiating coldstart)

When a coldstart node enters COLDSTART\_LISTEN, it listens to its attached channels.

If no communication is detected, the node enters the COLDSTART\_COLLISION\_RESOLUTION state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup frame. Since each coldstart node may perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a frame header during these four cycles, it re-enters the COLDSTART\_LISTEN state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup frames.

After four cycles in COLDSTART\_COLLISION\_RESOLUTION state, the node that initiated the coldstart enters the COLDSTART\_CONSISTENCY\_CHECK state. It collects all startup frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid startup frame pair, the node leaves COLDSTART\_CONSISTENCY\_CHECK and enters NORMAL\_ACTIVE state.

The number of coldstart attempts that a node is allowed to perform is configured by **SUCC1.CSA[4:0]**. The number of remaining coldstarts attempts can be read from **CCSV.RCA[4:0]**. The number of remaining coldstart attempts is reduced by one for each attempted coldstart. A node may enter the COLDSTART\_LISTEN state only if this value is larger than one and it may enter the COLDSTART\_COLLISION\_RESOLUTION state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

# 5.5.7.4 Path of following Coldstart Node (responding to leading Coldstart Node)

When a coldstart node enters the COLDSTART\_LISTEN state, it tries to receive a valid pair of startup frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid startup frame has been received the INITIALIZE\_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION\_COLDSTART\_CHECK state is entered.

In INTEGRATION\_COLDSTART\_CHECK state it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all sync frames and performs clock correction in the following doublecycle. If clock correction does not signal any errors and if the node continues to receive sufficient frames from the same node it has integrated on, the COLDSTART\_JOIN state is entered.

In COLDSTART\_JOIN state following coldstart nodes begin to transmit their own startup frames and continue to do so in subsequent cycles. Thereby, the leading coldstart node and the nodes joining it can check if their schedules agree with each other. If the clock correction signals any error, the node aborts the integration attempt. If a node in this state sees at least one valid startup frame during all even cycles in this state and at least one valid startup frame pair during all double cycles in this state, the node leaves COLDSTART\_JOIN state and enters NORMAL\_ACTIVE state. Thereby it leaves STARTUP at least one cycle after the node that initiated the coldstart.

# 5.5.7.5 Path of Non-coldstart Node

When a non-coldstart node enters the INTEGRATION\_LISTEN state, it listens to its attached channels.

As soon as a valid startup frame has been received, the INITIALIZE\_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION\_CONSISTENCY\_CHECK state is entered.

In INTEGRATION\_CONSISTENCY\_CHECK state the node verifies that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) are sending startup frames that agree with the node's own schedule. Clock correction is activated, and if any errors are signalled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup frames or the startup frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid startup frame pairs or the startup frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup frames are received within an even cycle, or less than two valid startup frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid startup frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL\_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

# 5.5.8 NORMAL\_ACTIVE State

E-Ray

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering STARTUP via coldstart path) and one additional node have entered the NORMAL\_ACTIVE state, the startup phase for the cluster has finished. In the NORMAL\_ACTIVE state, all configured messages are scheduled for transmission. This includes all data frames as well as the sync frames. Rate and offset measurement is started in all even cycles (even / odd cycle pairs required).

In NORMAL\_ACTIVE state the CC supports regular communication functions

- The CC performs transmissions and reception on the FlexRay bus as configured
- Clock synchronization is running
- The Host interface is operational

The CC exits from that state to

- HALT state by writing **SUCC1.CMD[3:0]** = "0110" (HALT command, at the end of the current cycle)
- HALT state by writing **SUCC1.CMD[3:0]** = "0111" (FREEZE command, immediately)
- HALT state due to change of the error state from ACTIVE to COMM\_HALT
- NORMAL\_PASSIVE state due to change of the error state from ACTIVE to PASSIVE
- READY state by writing **SUCC1.CMD[3:0]** = "0010" (READY command)

# 5.5.9 NORMAL\_PASSIVE State

NORMAL\_PASSIVE state is entered from NORMAL\_ACTIVE state when the error state changes from ACTIVE to PASSIVE.

In NORMAL\_PASSIVE state, the node is able to receive all frames (node is fully synchronized and performs clock synchronization). Contrary to the NORMAL\_ACTIVE state, the node does not actively participate in communication, i.e. neither symbols nor frames are transmitted.

In NORMAL\_PASSIVE state

- The CC performs reception on the FlexRay bus
- The CC does not transmit any frames or symbols on the FlexRay bus
- Clock synchronization is running
- The Host interface is operational

The CC exits from this state to

- HALT state by writing **SUCC1.CMD[3:0]** = "0110" (HALT command, at the end of the current cycle)
- HALT state by writing **SUCC1.CMD[3:0]** = "0111" (FREEZE command, immediately)
- HALT state due to change of the error state from PASSIVE to COMM\_HALT
- NORMAL\_ACTIVE state due to change of the error state from PASSIVE to ACTIVE. The transition takes place when **CCEV.PTAC**[4:0] equals **SUCC1.PTA**[4:0] - 1
- To READY state by writing **SUCC1.CMD[3:0]** = "0010" (READY command)

**BOSCH** 

# 5.5.10 HALT State

In this state all communication (reception and transmission) is stopped.

The CC enters this state

- By writing **SUCC1.CMD[3:0]** = "0110" (HALT command) while the CC is in NORMAL\_ACTIVE or NORMAL\_PASSIVE state
- By writing **SUCC1.CMD[3:0]** = "0111" (FREEZE command) from all states
- When exiting from NORMAL\_ACTIVE state because the clock correction failed counter reached the "maximum without clock correction fatal" limit
- When exiting from NORMAL\_PASSIVE state because the clock correction failed counter reached the "maximum without clock correction fatal" limit

The CC exits from this state to DEFAULT\_CONFIG state

• By writing **SUCC1.CMD[3:0]** = "0001" (CONFIG command)

When the CC enters HALT state, all configuration and status data is maintained for analysing purposes.

When the Host writes **SUCC1.CMD[3:0]** = "0110" (HALT command), the CC sets bit **CCSV.HRQ** and enters HALT state after the current communication cycle has finished.

When the Host writes **SUCC1.CMD[3:0]** = "0111" (FREEZE command), the CC enters HALT state immediately and sets bit **CCSV.FSI**.

The POC state from which the transition to HALT state took place can be read from CCSV.PSL[5:0].

# 5.6 Network Management

The accrued Network Management (NM) vector can be read from registers NMV1...3. The CC performs a bit-wise OR operation over all NM vectors out of all received valid NM frames with the Payload Preamble Indicator (**PPI**) bit set. Only static frames may be configured to hold NM information. The CC updates the NM vector at the end of each cycle.

The length of the NM vector can be configured from 0 to 12 bytes by **NEMC.NML[3:0]**. The NM vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay frames with the **PPI** bit set, bit **PPIT** in the header section of the respective transmit buffer has to be set via **WRHS1.PPIT**. In addition the Host has to write the NM information to the data section of the respective transmit buffer.

The evaluation of the NM vector has to be done by the application running on the Host.

**Note:** In case a message buffer is configured for transmission / reception of network management frames, the payload length configured in header 2 of that message buffer should be equal or greater than the length of the NM vector configured by **NEMC.NML[3:0]**.

When the CC transits to HALT state, the cycle count is not incremented and therefore the NM vector is not updated. In this case NMV1...3 holds the value from the cycle before.

# 5.7 Filtering and Masking

Filtering is done by comparison of the configuration of assigned message buffers against actual slot and cycle counter values and channel ID (channel A, B). A message buffer is only updated / transmitted if the required matches occur.

Filtering is done on:

• Slot Counter

E-Ray

- Cycle Counter
- Channel ID

The following filter combinations for acceptance / transmit filtering are allowed:

- Slot Counter + Channel ID
- Slot Counter + Cycle Counter + Channel ID

All configured filters must match in order to store a received message in a message buffer.

**Note:** For the FIFO the acceptance filter is configured by the FIFO Rejection Filter and the FIFO Rejection Filter Mask.

A message will be transmitted in the time slot corresponding to the configured frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

# 5.7.1 Slot Counter Filtering

Every transmit and receive buffer contains a frame ID stored in the header section. This frame ID is compared against the actual slot counter value in order to assign receive and transmit buffers to the corresponding slot.

If two or more message buffers are configured with the same frame ID, and if they have a matching cycle counter filter value for the same slot, then the message buffer with the **lowest** message buffer number is used.

manual\_functional\_description.fm

# 5.7.2 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in header section 1 of each message buffer.

If message buffer 0 resp. 1 is configured to hold the startup / sync frame or the single slot frame by bits **SUCC1.TXST**, **SUCC1.TXSY**, and **SUCC1.TSM**, cycle counter filtering for message buffer 0 resp. 1 must be disabled.

**Note:** Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay network is **not** allowed.

Cycle Code	Matching Cycle Counter Values											
0b000000x	all Cycles											
0b00000 <mark>1</mark> c	every second Cycle	at (Cycle Count)mod2	= C									
0b00001cc	every fourth Cycle	at (Cycle Count)mod4	= CC									
0b0001ccc	every eighth Cycle	at (Cycle Count)mod8	= CCC									
0b001cccc	every sixteenth Cycle	at (Cycle Count)mod16	= CCCC									
0b01ccccc	every thirty-second Cycle	at (Cycle Count)mod32	= CCCCC									
0b1cccccc	every sixty-fourth Cycle	at (Cycle Count)mod64	= CCCCCC									

The set of cycle numbers belonging to a cycle set is determined as described in Table 9.

# Table 9: Definition of cycle set

Table 10 below gives some examples for valid cycle sets to be used for cycle counter filtering:

Cycle Code	Matching Cycle Counter Values
0b0000011	1-3-5-763 ,⊣
0b0000100	0-4-8-1260 ₊J
0b0001110	6-14-22-3062 ,⊣
0b0011000	8-24-40-56 ,
0b0100011	3-35 -1
0b1001001	ل 9

 Table 10: Examples for valid cycle sets

The received message is stored only if the cycle counter value of the cycle during which the message is received matches an element of the receive buffer's cycle set. Other filter criteria must also be met.

The content of a transmit buffer is transmitted on the configured channel(s) when an element of the cycle set matches the current cycle counter value. Other filter criteria must also be met.

### E-Ray

# 5.7.3 Channel ID Filtering

There is a 2-bit channel filtering field (**CHA**, **CHB**) located in the header section of each message buffer in the Message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see Table 11).

СНА	СНВ	Transmit Buffer transmit frame	Receive Buffer store valid receive frame
1	1	on both channels (static segment only)	received on channel A or B (store first semantically valid frame, static segment only)
1	0	on channel A	received on channel A
0	1	on channel B	received on channel B
0	0	no transmission	ignore frame

### Table 11: Channel filtering configuration

The contents of a transmit buffer is transmitted on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be set up for transmission on both channels (**CHA** and **CHB** set).

Valid received frames are stored if they are received on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a receive buffer may be setup for reception on both channels (**CHA** and **CHB** set).

**Note:** If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to '1', no frames are transmitted resp. received frames are ignored (same function as **CHA = CHB** = '0').

# 5.7.4 FIFO Filtering

For FIFO filtering there is one rejection filter and one rejection filter mask available. The FIFO filter consists of channel filter **FRF.CH[1:0]**, frame ID filter **FRF.FID[10:0]**, and cycle counter filter **FRF.CYF[6:0]**. Registers FRF and FRFM can be configured in DEFAULT\_CONFIG or CONFIG state only. The filter configuration in the header section of message buffers belonging to the FIFO is ignored.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles **not** belonging to the cycle set specified by **FRF.CYF[6:0]**, **all** frames are rejected.

A valid received frame is stored in the FIFO if channel ID, frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

# 5.8 Transmit Process

# 5.8.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the frame ID corresponding to the next sending slot is selected for transmission.

The data section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

# 5.8.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest frame ID) is selected next. In the dynamic segment different slot counter sequences on channel A and channel B are possible (concurrent sending of different frame IDs on both channels).

The data section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

The start of latest transmit configured by **MHDC.SLT[12:0]** defines the maximum minislot value allowed before inhibiting new frame transmission in the dynamic segment of the current cycle.

# 5.8.3 Transmit Buffers

E-Ray message buffers can be configured as transmit buffers by programming bit **CFG** in the header section of the respective message buffer to '1' via WRHS1.

There exist the following possibilities to assign a transmit buffer to the CC channels:

- Static segment: channel A **or** channel B, channel A **and** channel B
- Dynamic segment: channel A **or** channel B

Message buffer 0 resp. 1 is dedicated to hold the startup frame, the sync frame, or the designated single slot frame as configured by **SUCC1.TXST**, **SUCC1.TXSY**, and **SUCC1.TSM**. In this case, it can be reconfigured in DEFAULT\_CONFIG or CONFIG state only. This ensures that any node transmits at most one startup / sync frame per communication cycle. Transmission of startup / sync frames from other message buffers is not possible.

All other message buffers configured for transmission in static or dynamic segment are reconfigurable during runtime depending on the configuration of **MRC.SEC[1:0]** (see 5.11.1 Reconfiguration of Message Buffers). Due to the organization of the data partition in the Message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the header section of a message buffer may lead to erroneous configurations.

If a message buffer is reconfigured (header section updated) during runtime, it may happen that this message buffer is not send out in the respective communication cycle.

The CC does not have the capability to calculate the header CRC. The Host is supposed to provide the header CRCs for all transmit buffers. If network management is required, the Host has to set the **PPIT** bit in the header section of the respective message buffer to '1' and write the network management information to the data section of the message buffer (see 5.6 Network Management).

The payload length field configures the payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by **MHDC.SFDL[6:0]**, the CC generates padding bytes to ensure that frames have proper physical length. The padding pattern is logical zero.

Each transmit buffer provides a transmission mode flag **TXM** that allows the Host to configure the transmission mode for the transmit buffer. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode.

In **single-shot mode** the CC resets the respective **TXR** flag after transmission has completed. Now the Host may update the transmit buffer.

In **continuous mode**, the CC does not reset the respective transmission request flag **TXR** after successful transmission. In this case a frame is sent out each time the filter criteria match. The **TXR** flag can be reset by the Host by writing the respective message buffer number to the IBCR register while bit **IBCM.STXRH** is set to '0'.

If two or more transmit buffers meet the filter criteria simultaneously, the transmit buffer with the lowest message buffer number will be transmitted in the respective slot.

# 5.8.4 Frame Transmission

The following steps are required to prepare a message buffer for transmission:

- Configure the transmit buffer in the Message RAM via WRHS1, WRHS2, and WRHS3
- Write the data section of the transmit buffer via WRDSn
- Transfer the configuration and message data from Input Buffer to the Message RAM by writing the number of the target message buffer to register IBCR
- If configured in register IBCM, the transmission request flag **TXR** for the respective message buffer will be set as soon as the transfer has completed, and the message buffer is ready for transmission.
- Check whether the message buffer has been transmitted by checking the respective **TXR** bit  $(\mathbf{TXR} = '0')$  in the TRXQ1/2/3/4 registers (single-shot mode only).

After transmission has completed, the respective **TXR** flag in the TXRQ1/2/3/4 register is reset (single-shot mode), and, if bit **MBI** in the header section of the message buffer is set, flag **SIR.TXI** is set to '1'. If enabled, an interrupt is generated.

# 5.8.5 Null Frame Transmission

If in static segment the Host does not set the transmission request flag before transmit time, and if there is no other transmit buffer with matching filter criteria, the CC transmits a null frame with the null frame indication bit **set to '0'** and the payload data **set to zero**.

In the following cases the CC transmits a null frame:

- If the message buffer with the lowest message buffer number matching the filter criteria does not have its transmission request flag set ( $\mathbf{TXR} = '0'$ ).
- No transmit buffer configured for the slot has a cycle counter filter that matches the current cycle. In this case, no message buffer status MBS is updated.

Null frames are not transmitted in the dynamic segment.

# 5.9 Receive Process

# 5.9.1 Dedicated Receive Buffers

A portion of the E-Ray message buffers can be configured as dedicated receive buffers by programming bit **CFG** in the header section of the respective message buffer to '0' via WRHS1.

The following possibilities exist to assign a receive buffer to the CC channels:

- Static segment: channel A or channel B,
  - channel A and channel B (the CC stores the first semantically valid frame)
- Dynamic segment: channel A or channel B

The CC transfers the payload data of valid received messages from the shift register of the FlexRay channel protocol controller (channel A or B) to the receive buffer with the matching filter configuration. A receive buffer stores all frame elements except the frame CRC.

All message buffers configured for reception in static or dynamic segment are reconfigurable during runtime depending on the configuration of **MRC.SEC**[1:0] (see 5.11.1 Reconfiguration of Message Buffers). If a message buffer is reconfigured (header section updated) during runtime it may happen that in the respective communication cycle a received message is lost.

If two or more receive buffers meet the filter criteria simultaneously, the receive buffer with the lowest message buffer number is updated with the received message.

# 5.9.2 Frame Reception

The following steps are required to prepare a dedicated message buffer for reception:

- Configure the receive buffer in the Message RAM via WRHS1, WRHS2, and WRHS3
- Transfer the configuration from Input Buffer to the Message RAM by writing the number of the target message buffer to register IBCR

Once these steps are performed, the message buffer functions as an active receive buffer and participates in the internal acceptance filtering process which takes place every time the CC receives a message. The first matching receive buffer is updated from the received message.

If a valid payload segment was stored in the data section of a message buffer, the respective **ND** flag in the NDAT1/2/3/4 registers is set, and, if bit **MBI** in the header section of that message buffer is set, flag **SIR.RXI** is set to '1'. If enabled, an interrupt is generated.

In case that bit **ND** was already set when the Message Handler updates the message buffer, bit **MBS.MLST** of the respective message buffer is set and the unprocessed message data is lost.

If no frame, a null frame, or a corrupted frame was received in a slot, the data section of the message buffer configured for this slot is not updated. In this case only the respective message buffer status MBS is updated.

When the Message Handler changed the message buffer status MBS in the header section of a message buffer, the respective **MBC** flag in the MBSC1/2/3/4 registers is set, and if bit **MBI** in the header section of that message buffer is set, flag **SIR.MBSI** is set to '1'. If enabled an interrupt is generated.

🕪 BOSCH

If the payload length of a received frame **PLR[6:0]** is longer than the value programmed by **PLC[6:0]** in the header section of the respective message buffer, the data field stored in the message buffer is truncated to that length.

To read a receive buffer from the Message RAM via the Output Buffer, proceed as described in 5.11.2.2 Data Transfer from Message RAM to Output Buffer.

**Note:** The **ND** and **MBC** flags are automatically cleared by the Message Handler when the payload data and the header of a received message have been transferred to the Output Buffer, respectively.

# 5.9.3 Null Frame Reception

The payload segment of a received null frame is **not** copied into the matching dedicated receive buffer. If a null frame has been received, only the message buffer status MBS of the matching message buffer is updated from the received null frame. All bits in header 2 and 3 of the matching message buffer remain unchanged. They are updated from received data frames only.

When the Message Handler changed the message buffer status MBS in the header section of a message buffer, the respective **MBC** flag in the MBSC1/2/3/4 register is set, and if bit **MBI** in the header section of that message buffer is set, flag **SIR.MBSI** is set to '1'. If enabled, an interrupt is generated.

# 5.10 FIFO Function

# 5.10.1 Description

A group of the message buffers can be configured as a cyclic First-In-First-Out (FIFO) buffer. The group of message buffers belonging to the FIFO is contiguous in the register map starting with the message buffer referenced by **MRC.FFB[7:0]** and ending with the message buffer referenced by **MRC.LCB[7:0]**. Up to 128 message buffers can be assigned to the FIFO.

Every **valid** incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case frame ID, payload length, receive cycle count, and the message buffer status MBS of the addressed FIFO message buffer are overwritten with frame ID, payload length, receive cycle count, and the status from the received frame. Bit **SIR.RFNE** shows that the FIFO is not empty, bit **SIR.RFCL** is set when the receive FIFO fill level **FSR.RF-FL[7:0]** is equal or greater than the critical level as configured by **FCL.CL[7:0]**, bit **EIR.RFO** shows that a FIFO overrun has been detected. If enabled, interrupts are generated.

If null frames are not rejected by the FIFO rejection filter, the null frames will be treated like data frames when they are stored into the FIFO.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the message buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available message buffer. If the PIDX register is incremented past the highest numbered message buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) message buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next message buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a message buffer belonging to the FIFO to the Output Buffer. The PUT Index Register and the GET Index Register are not accessible by the Host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message overwrites the oldest message in the FIFO. This will set FIFO overrun flag **EIR.RFO**.

A FIFO non empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag **SIR.RFNE** is set. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in Figure 8 for a three message buffer FIFO.

The programmable FIFO Rejection Filter (FRF) defines a filter pattern for messages to be rejected. The FIFO filter consists of channel filter, frame ID filter, and cycle counter filter. If bit **FRF.RSS** is set to '1' (default), all messages received in the static segment are rejected by the FIFO. If bit **FRF.RNF** is set to '1' (default), received null frames are not stored in the FIFO.

The FIFO Rejection Filter Mask (FRFM) specifies which bits of the frame ID filter in the FIFO Rejection Filter register are marked 'don't care' for rejection filtering.

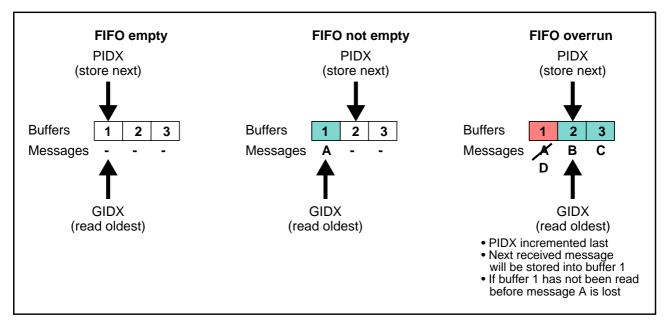

Figure 8: FIFO status: empty, not empty, overrun

# 5.10.2 Configuration of the FIFO

(Re)configuration of message buffers belonging to the FIFO is only possible when the CC is in DEFAULT\_CONFIG or CONFIG state. While the CC is in DEFAULT\_CONFIG or CONFIG state, the FIFO function is not available.

For all message buffers belonging to the FIFO the payload length configured should be programmed to the same value via **WRHS2.PLC[6:0]**. The data pointer to the first 32-bit word of the data section of the respective message buffer in the Message RAM has to be configured via **WRHS3.DP[10:0]**.

All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask. The values configured in the header sections of the message buffers belonging to the FIFO are, with exception of DP and PLC, irrelevant.

**Note:** It is recommended to program the MBI bits of the message buffers belonging to the FIFO to '0' via **WRHS1.MBI** to avoid generation of RX interrupts.

If the payload length of a received frame is longer than the value programmed by **WRHS2.PLC[6:0]** in the header section of the respective message buffer, the data field stored in a message buffer of the FIFO is truncated to that length.

# 5.10.3 Access to the FIFO

For FIFO access outside DEFAULT\_CONFIG and CONFIG state, the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first message buffer of the FIFO (referenced by **MRC.FFB[7:0]**) to the register OBCR. The Message Handler then transfers the message buffer addressed by the GET Index Register (GIDX) to the Output Buffer. After this transfer the GET Index Register (GIDX) is incremented.

# 5.11 Message Handling

The Message Handler controls data transfers between the Input / Output Buffer and the Message RAM and between the Message RAM and the two Transient Buffer RAMs. All accesses to the internal RAMs are 32+1 bit accesses. The additional bit is used for parity checking.

Access to the message buffers stored in the Message RAM is done under control of the Message Handler state machine. This avoids conflicts between accesses of the two FlexRay channel protocol controllers and the Host to the Message RAM.

Frame IDs of message buffers assigned to the static segment have to be in the range from 1 to **GTUC7.NSS[9:0]**. Frame IDs of message buffers assigned to the dynamic segment have to be in the range from **GTUC7.NSS[9:0]** + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

# 5.11.1 Reconfiguration of Message Buffers

In case that an application needs to operate with more than 128 different messages, static and dynamic message buffers may be reconfigured during FlexRay operation. This is done by updating the header section of the respective message buffer via Input Buffer registers WRHS1...3.

Reconfiguration has to be enabled via control bits **MRC.SEC[1:0]** in the Message RAM Configuration register.

If a message buffer has not been transmitted / updated from a received frame before reconfiguration starts, the respective message is lost.

The point in time when a reconfigured message buffer is ready for transmission / reception according to the reconfigured frame ID depends on the actual state of the slot counter when the update of the header section has completed. Therefore it may happen that a reconfigured message buffer is not transmitted / updated from a received frame in the cycle where it was reconfigured.

The Message RAM is scanned according to Table 6 below:

Start of Scan in Slot	Scan for Slots
1	215, 1 (next cycle)
8	1623, 1 (next cycle)
16	2431, 1 (next cycle)
24	3239, 1 (next cycle)

### Table 12: Scan of Message RAM

A Message RAM scan is terminated with the start of NIT regardless whether it has completed or not. The scan of the Message RAM for slots 2 to 15 starts at the beginning of slot 1 of the actual cycle. The scan of the Message RAM for slot 1 is done in the cycle before by checking in parallel to each scan of the Message RAM whether there is a message buffer configured for slot 1 of the next cycle.

The number of the first dynamic message buffer is configured by **MRC.FDB**[7:0]. In case a Message RAM scan starts while the CC is in dynamic segment, the scan starts with the message buffer number configured by **MRC.FDB**[7:0].

manual\_functional\_description.fm

In case a message buffer should be reconfigured to be used in slot 1 of the next cycle, the following has to be considered:

- If the message buffer to be reconfigured for slot 1 is part of the "Static Buffers", it will only be found if it is reconfigured before the last Message RAM scan in the static segment of the actual cycle evaluates this message buffer.
- If the message buffer to be reconfigured for slot 1 is part of the "Static + Dynamic Buffers", it will be found if it is reconfigured before the last Message RAM scan in the actual cycle evaluates this message buffer.
- The start of NIT terminates the Message RAM scan. In case the Message RAM scan has not evaluated the reconfigured message buffer until this point in time, the message buffer will not be considered for the next cycle.
- **Note:** Reconfiguration of message buffers may lead to the loss of messages and therefore has to be used very carefully. In worst case (reconfiguration in consecutive cycles) it may happen that a message buffer is never transmitted / updated from a received frame.

# 5.11.2 Host access to Message RAM

The message transfer between Input Buffer and Message RAM as well as between Message RAM and Output Buffer is triggered by the Host by writing the number of the target / source message buffer to be accessed to IBCR or OBCR register.

The IBCM and OBCM registers can be used to write / read header and data section of the selected message buffer separately.

If bit **IBCM.STXR** is set to = '1', the transmission request flag **TXR** of the selected message buffer is automatically set after the message buffer has been updated. If bit **IBCM.STXR** is reset to '0', the transmission request flag **TXR** of the selected message buffer is reset. This can be used to stop transmission from message buffers operated in continuous mode.

Input Buffer (IBF) and Output Buffer (OBF) are build up as a double buffer structure. One half of this double buffer structure is accessible by the Host (IBF Host / OBF Host), while the other half (IBF Shadow / OBF Shadow) is accessed by the Message Handler for data transfers between IBF / OBF and Message RAM.

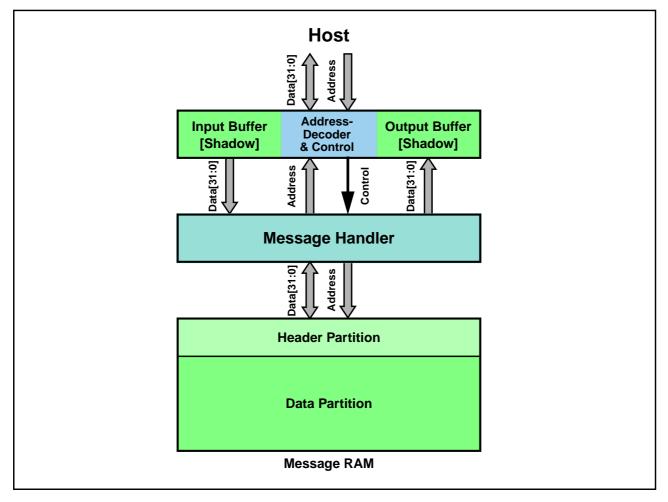

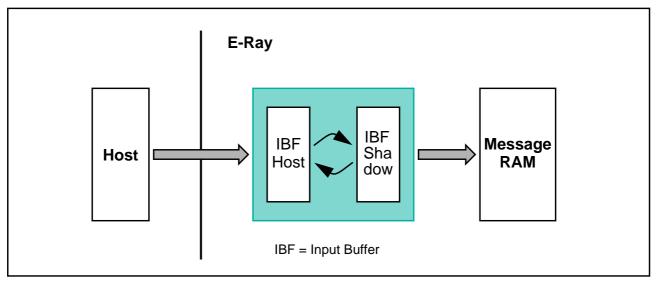

Figure 9: Host access to Message RAM

nanual\_functional\_description.fm

# 5.11.2.1 Data Transfer from Input Buffer to Message RAM

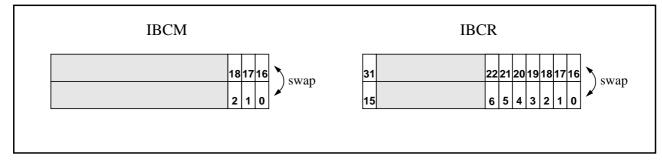

To configure / update a message buffer in the Message RAM, the Host has to write the data to WRDSn and the header to WRHS1...3. The specific action is selected by configuring the Input Buffer Command Mask IBCM.

When the Host writes the number of the target message buffer in the Message RAM to **IBCR.IBRH[6:0]**, IBF Host and IBF Shadow are swapped (see Figure 10).

### Figure 10: Double buffer structure Input Buffer

In addition the bits in the IBCM and IBCR registers are also swapped to keep them attached to the respective IBF section (see Figure 11).

# Figure 11: Swapping of IBCM and IBCR bits

With this write operation bit **IBCR.IBSYS** is set to '1'. The Message Handler then starts to transfer the contents of IBF Shadow to the message buffer in the Message RAM selected by **IBCR.IBRS[6:0**].

While the Message Handler transfers the data from IBF Shadow to the target message buffer in the Message RAM, the Host may write the next message to IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, bit **IBCR.IBSYS** is set back to '0' and the next transfer to the Message RAM may be started by the Host by writing the respective target message buffer number to **IBCR.IBRH[6:0]**.

E-Ray

E-Ray

If a write access to **IBCR.IBRH[6:0]** occurs while **IBCR.IBSYS** is '1', **IBCR.IBSYH** is set to '1'. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, **IBCR.IBSYH** is reset to '0', **IBCR.IBSYS** remains set to '1', and the next transfer to the Message RAM is started. In addition the message buffer numbers stored under **IBCR.IBRH[6:0]** and **IBCR.IBRS[6:0]** and the command mask flags are also swapped.

# Example of a 8/16/32-bit Host access sequence:

Configure / update n-th message buffer via IBF

- Wait until IBCR.IBSYH is reset
- Write data section to WRDSn
- Write header section to WRHS1...3
- Write Command Mask: write IBCM.STXRH, IBCM.LDSH, IBCM.LHSH
- Demand data transfer to target message buffer: write **IBCR.IBRH[6:0**]

Configure / update (n+1)th message buffer via IBF

- Wait until IBCR.IBSYH is reset
- Write data section to WRDSn
- Write header section to WRHS1...3
- Write Command Mask: write IBCM.STXRH, IBCM.LDSH, IBCM.LHSH
- Demand data transfer to target message buffer: write **IBCR.IBRH[6:0**]

•••

**Note:** Any write access to IBF while **IBCR.IBSYH** is '1' will set error flag **EIR.IIBA** to '1'. In this case the write access has no effect.

Pos.	Access	Bit	Function
18	r	STXRS	Set Transmission Request Shadow ongoing or finished
17	r	LDSS	Load Data Section Shadow ongoing or finished
16	r	LHSS	Load Header Section Shadow ongoing or finished
2	r/w	STXRH	Set Transmission Request Host
1	r/w	LDSH	Load Data Section Host
0	r/w	LHSH	Load Header Section Host

### Table 13: Assignment of IBCM bits

Pos.	Access	Bit	Function
31	r	IBSYS	IBF Busy Shadow, signals ongoing transfer from IBF Shadow to Message RAM
2216	r	IBRS[6:0]	IBF Request Shadow, number of message buffer currently / lately updated
15	r	IBSYH	IBF Busy Host, transfer request pending for message buffer referenced by IBRH[6:0]
60	r/w	IBRH[6:0]	IBF Request Host, number of message buffer to be updated next

 Table 14: Assignment of IBCR bits

# 5.11.2.2 Data Transfer from Message RAM to Output Buffer

To read a message buffer from the Message RAM, the Host has to write to register OBCR to trigger the data transfer as configured in OBCM. After the transfer has completed, the Host can read the transferred data from RDDSn, RDHS1...3, and MBS.

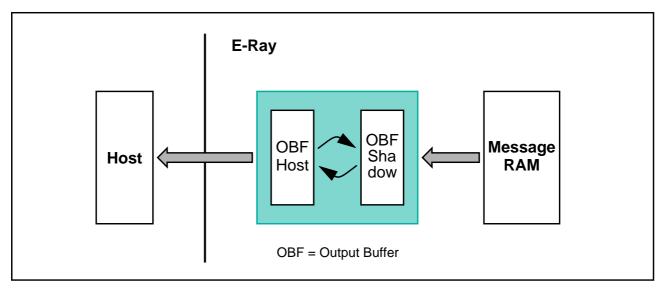

Figure 12: Double buffer structure Output Buffer

OBF Host and OBF Shadow as well as bits **OBCM.RHSS**, **OBCM.RDSS**, **OBCM.RHSH**, **OBCM.RDSH** and bits **OBCR.OBRS**[6:0], **OBCR.OBRH**[6:0] are swapped under control of bits **OBCR.VIEW** and **OBCR.REQ**.

Writing bit **OBCR.REQ** to '1' copies bits **OBCM.RHSS**, **OBCM.RDSS** and bits **OBCR.OBRS[6:0]** to an internal storage (see Figure 13).

After setting **OBCR.REQ** to '1', **OBCR.OBSYS** is set to '1', and the transfer of the message buffer selected by **OBCR.OBRS[6:0]** from the Message RAM to OBF Shadow is started. After the transfer between the Message RAM and OBF Shadow has completed, the **OBCR.OBSYS** bit is set back to '0'. Bits **OBCR.REQ** and **OBCR.VIEW** can only be set to '1' while **OBCR.OBSYS** is '0'.

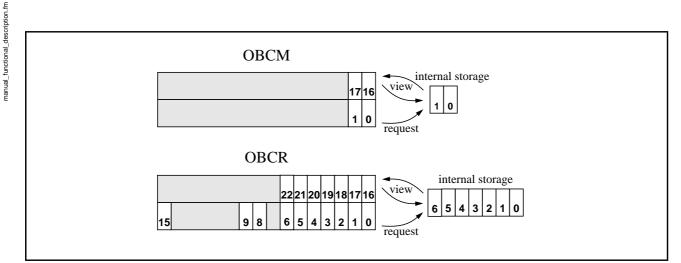

Figure 13: Swapping of OBCM and OBCR bits

OBF Host and OBF Shadow are swapped by setting bit **OBCR.VIEW** to '1' while bit **OBCR.OB-SYS** is '0' (see Figure 12).

In addition bits **OBCR.OBRH[6:0]** and bits **OBCM.RHSH**, **OBCM.RDSH** are swapped with the registers internal storage thus assuring that the message buffer number stored in **OBCR.OBRH[6:0]** and the mask configuration stored in **OBCM.RHSH**, **OBCM.RDSH** matches the transferred data stored in OBF Host (see Figure 13).

Now the Host can read the transferred message buffer from OBF Host while the Message Handler may transfer the next message from the Message RAM to OBF Shadow.

# Example of an 8/16/32-bit Host access to a single message buffer:

If a single message buffer has to be read out, two separate write accesses to **OBCR.REQ** and **OBCR.VIEW** are necessary:

- Wait until **OBCR.OBSYS** is reset
- Write Output Buffer Command Mask OBCM.RHSS, OBCM.RDSS
- Request transfer of message buffer to OBF Shadow by writing **OBCR.OBRS[6:0]** and **OBCR.REQ** (in case of and 8-bit Host interface, **OBCR.OBRS[6:0]** has to be written **before OBCR.REQ**).
- Wait until OBCR.OBSYS is reset
- Toggle OBF Shadow and OBF Host by writing **OBCR.VIEW** = '1'
- Read out transferred message buffer by reading RDDSn, RDHS1...3, and MBS

# Example of an 8/16/32-bit Host access sequence:

Request transfer of 1st message buffer to OBF Shadow

- Wait until **OBCR.OBSYS** is reset
- Write Output Buffer Command Mask OBCM.RHSS, OBCM.RDSS for 1st message buffer
- Request transfer of 1st message buffer to OBF Shadow by writing **OBCR.OBRS[6:0]** and **OBCR.REQ** (in case of an 8-bit Host interface, **OBCR.OBRS[6:0]** has to be written **before OBCR.REQ**).

Toggle OBF Shadow and OBF Host to read out 1st transferred message buffer and request transfer of 2nd message buffer:

- Wait until OBCR.OBSYS is reset
- Write Output Buffer Command Mask OBCM.RHSS, OBCM.RDSS for 2nd message buffer
- Toggle OBF Shadow and OBF Host and start transfer of 2nd message buffer to OBF Shadow simultaneously by writing **OBCR.OBRS[6:0]** of 2nd message buffer, **OBCR.REQ**, and **OBCR.VIEW** (in case of and 8-bit Host interface, **OBCR.OBRS[6:0]** has to be written **before OBCR.REQ** and **OBCR.VIEW**).
- Read out 1st transferred message buffer by reading RDDSn, RDHS1...3, and MBS

•••

Demand access to last requested message buffer without request of another message buffer:

- Wait until OBCR.OBSYS is reset
- Demand access to last transferred message buffer by writing **OBCR.VIEW**
- Read out last transferred message buffer by reading RDDSn, RDHS1...3, and MBS

Pos.	Access	Bit	Function
17	r	RDSH	Data Section available for Host access
16	r	RHSH	Header Section available for Host access
1	r/w	RDSS	Read Data Section Shadow
0	r/w	RHSS	Read Header Section Shadow

### Table 15: Assignment of OBCM bits

nanual\_functional\_description.fm

Pos.	Access	Bit	Function

60	r/w	OBRS[6:0]	OBF Request Shadow, number of message buffer for next request

 Table 16: Assignment of OBCR bits

# 5.11.3 FlexRay Protocol Controller access to Message RAM

The two Transient Buffer RAMs (TBF A,B) are used to buffer the data for transfer between the two FlexRay Protocol Controllers and the Message RAM.

Each Transient Buffer RAM is build up as a double buffer, able to store two complete FlexRay messages. There is always one buffer assigned to the corresponding Protocol Controller while the other one is accessible by the Message Handler.

If e.g. the Message Handler writes the next message to be send to Transient Buffer Tx, the FlexRay Channel Protocol Controller can access Transient Buffer Rx to store the message it is actually receiving. During transmission of the message stored in Transient Buffer Tx, the Message Handler transfers the last received message stored in Transient Buffer Rx to the Message RAM (if it passes acceptance filtering) and updates the respective message buffer.

Data transfers between the Transient Buffer RAMs and the shift registers of the FlexRay Channel Protocol Controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay messages.

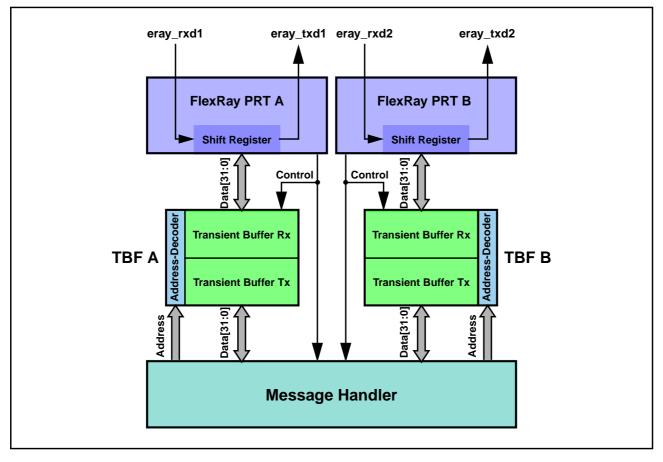

Figure 14: Access to Transient Buffer RAMs

nanual\_functional\_description.fm

# 5.12 Message RAM

To avoid conflicts between Host access to the Message RAM and FlexRay message reception / transmission, the Host cannot directly access the message buffers in the Message RAM. These accesses are handled via the Input and Output Buffers. The Message RAM is able to store up to 128 message buffers depending on the configured payload length.

The Message RAM is organized  $2048 \times 33 = 67,584$  bit. Each 32-bit word is protected by a parity bit. To achieve the required flexibility with respect to different numbers of data bytes per FlexRay frame (0...254), the Message RAM has a structure as shown in Figure 15.

The data partition is allowed to start at Message RAM word number: (MRC.LCB + 1) • 4

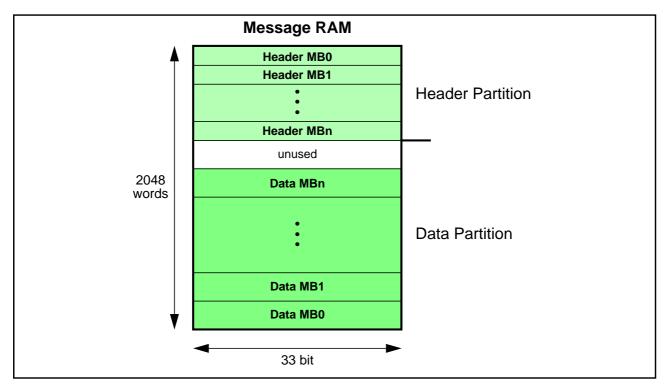

Figure 15: Configuration example of message buffers in the Message RAM

# **Header Partition**

Stores header sections of the configured message buffers:

- Supports a maximum of 128 message buffers
- Each message buffer has a header section of four 32+1 bit words
- Header 3 of each message buffer holds the 11-bit data pointer to the respective data section in the data partition

# **Data Partition**

Flexible storage of data sections with different length. Some maximum values are:

- 30 message buffers with 254 byte data section each
- Or 56 message buffers with 128 byte data section each
- Or 128 message buffers with 48 byte data section each

**Restriction:** header partition + data partition may not occupy more than 2048 33-bit words.

# 5.12.1 Header Partition

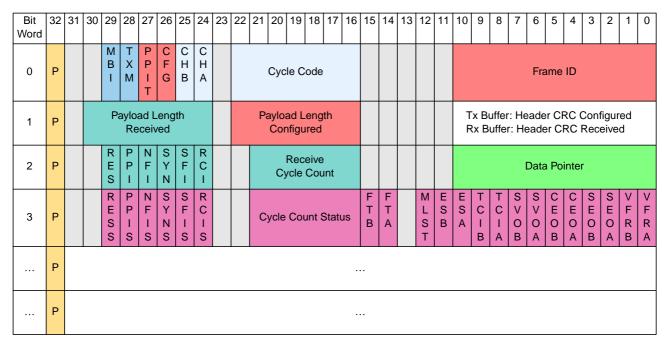

The elements used for configuration of a message buffer as well as the actual message buffer status are stored in the header partition of the Message RAM as listed in Table 17 below. Configuration of the header sections of the message buffers is done via IBF (WRHS1...3). Read access to the header sections is done via OBF (RDHS1...3 + MBS). The data pointer has to be calculated by the programmer to define the starting point of the data section for the respective message buffer in the data partition of the Message RAM. The data pointer should not be modified during runtime. For message buffers belonging to the receive FIFO (re)configuration is possible in DEFAULT\_CONFIG or CONFIG state only.

The header section of each message buffer occupies four 33-bit words in the header partition of the Message RAM. The header of message buffer 0 starts with the first word in the Message RAM.

For transmit buffers the Header CRC has to be calculated by the Host.

Payload Length Received **PLR[6:0]**, Receive Cycle Count **RCC[5:0]**, Received on Channel Indicator **RCI**, Startup Frame Indicator **SFI**, Sync Frame Indicator **SYN**, Null Frame Indicator **NFI**, Payload Preamble Indicator **PPI**, and Reserved Bit **RES** are updated from received valid data frames only.

Header word 3 of each configured message buffer holds the respective Message Buffer Status MBS.

manual\_functional\_description.fm

# 5.12.2 Data Partition

The data partition of the Message RAM stores the data sections of the message buffers configured for reception / transmission as defined in the header partition. The number of data bytes for each message buffer can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay Protocol Controllers and the Message RAM as well as between the Host interface and the Message RAM, the physical width of the Message RAM is set to 4 bytes plus one parity bit.

The data partition starts after the last word of the header partition. When configuring the message buffers in the Message RAM the programmer has to assure that the data pointers point to addresses within the data partition. Table 18 below shows an example how the data sections of the configured message buffers can be stored in the data partition of the Message RAM.

The beginning and the end of a message buffer's data section is determined by the data pointer and the payload length configured in the message buffer's header section, respectively. This enables a flexible usage of the available RAM space for storage of message buffers with different data length.

If the size of the data section is an odd number of 2-byte words, the remaining 16 bits in the last 32bit word are unused (see Table 18 below).

Bit Word	32	31	30	) 29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 18: Example for structure of the data partition in the Message RAM

### 5.12.3 Parity Check

There is a parity checking mechanism implemented in the E-Ray core to assure the integrity of the data stored in the seven RAM blocks. The RAM blocks have a parity generator / checker attached as shown in Figure 16. When data is written to a RAM block, the local parity generator generates the parity bit. The E-Ray core uses an even parity (with an even number of ones in the 32-bit data word a zero parity bit is generated). The parity bit is stored together with the respective data word. The parity is checked each time a data word is read from any of the RAM blocks. The E-Ray core's internal data buses have a width of 32 bits.

If a parity error is detected, the respective error flag is set. The parity error flags **MHDS.PIBF**, **MHDS.POBF**, **MHDS.PMR**, **MHDS.PTBF1**, **MHDS.PTBF2**, and the faulty message buffer indicators **MHDS.FMBD**, **MHDS.MFMB**, **MHDS.FMB**[6:0] are located in the Message Handler Status register. These single error flags control the error interrupt flag **EIR.PERR**.

Figure 16 shows the data paths between the RAM blocks and the parity generators / checkers.

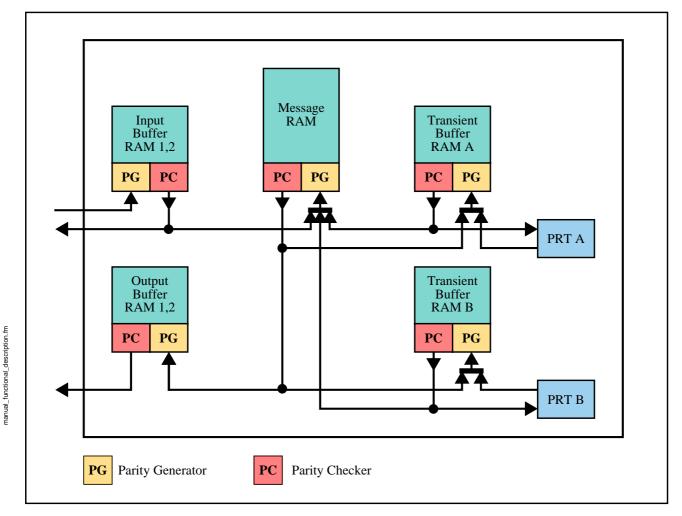

Figure 16: Parity generation and check

**Note:** Parity generator & checker are not part of the RAM blocks, but of the RAM access logic which is part of the E-Ray core.

When a parity error has been detected the following actions will be performed:

#### In all cases

- The respective parity error flag in register MHDS is set
- The parity error flag **EIR.PERR** is set and, if enabled, a module interrupt to the Host will be generated.

#### Additionally in specific cases

- 1) Parity error during data transfer from Input Buffer RAM  $1,2 \Rightarrow$  Message RAM
- a) Transfer of header and data section:
- MHDS.PIBF bit is set
- MHDS.FMBD bit is set to indicate that MHDS.FMB[6:0] points to a faulty message buffer
- MHDS.FMB[6:0] indicates the number of the faulty message buffer
- Transmit buffer: Transmission request for the respective message buffer is not set
- b) Transfer of data section only:

Parity error when reading header section of respective message buffer from Message RAM.

- MHDS.PMR bit is set
- MHDS.FMBD bit is set to indicate that MHDS.FMB[6:0] points to a faulty message buffer
- MHDS.FMB[6:0] indicates the number of the faulty message buffer
- The data section of the respective message buffer is not updated
- Transmit buffer: Transmission request for the respective message buffer is not set
- 2) Parity error during Host reading Input Buffer RAM 1,2
- MHDS.PIBF bit is set
- 3) Parity error during scan of header sections in Message RAM
- MHDS.PMR bit is set
- MHDS.FMBD bit is set to indicate that MHDS.FMB[6:0] points to a faulty message buffer
- MHDS.FMB[6:0] indicates the number of the faulty message buffer
- Ignore message buffer (message buffer is skipped)
- 4) Parity error during data transfer from Message RAM  $\Rightarrow$  Transient Buffer RAM 1, 2
- MHDS.PMR bit is set
- MHDS.FMBD bit is set to indicate that MHDS.FMB[6:0] points to a faulty message buffer
- MHDS.FMB[6:0] indicates the number of the faulty message buffer
- Frame not transmitted, frames already in transmission are invalidated by setting the frame CRC to zero

5) Parity error during data transfer from Transient Buffer RAM 1,  $2 \Rightarrow$  Protocol Controller 1, 2

- MHDS.PTBF1,2 bit is set
- Frames already in transmission are invalidated by setting the frame CRC to zero

- 6) Parity error during data transfer from Transient Buffer RAM 1,  $2 \Rightarrow$  Message RAM
- a) Parity error when reading header section of respective message buffer from Message RAM:
- MHDS.PMR bit is set
- MHDS.FMBD bit is set to indicate that MHDS.FMB[6:0] points to a faulty message buffer
- MHDS.FMB[6:0] indicates the number of the faulty message buffer
- The data section of the respective message buffer is not updated

b) Parity error when reading Transient Buffer RAM 1, 2:

- MHDS.PTBF1,2 bit is set
- MHDS.FMBD bit is set to indicate that MHDS.FMB[6:0] points to a faulty message buffer
- MHDS.FMB[6:0] indicates the number of the faulty message buffer

7) Parity error during data transfer from Message RAM  $\Rightarrow$  Output Buffer RAM

- MHDS.PMR bit is set
- MHDS.FMBD bit is set to indicate that MHDS.FMB[6:0] points to a faulty message buffer
- MHDS.FMB[6:0] indicates the number of the faulty message buffer

8) Parity error during Host reading Output Buffer RAM 1,2

• MHDS.POBF bit is set

9) Parity error during data read of Transient Buffer RAM 1, 2

When a parity error occurs when the Message Handler reads a frame with network management information (PPI = '1') from the Transient Buffer RAM 1, 2 the corresponding network management vector register NMV1...3 is not updated from that frame.

## 5.13 Module Interrupt

E-Ray

In general, interrupts provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the CC, a frame is received or transmitted, a configured timer interrupt is activated, or a stop watch event occurred. This enables the Host to react very quickly on specific error conditions, status changes, or timer events. On the other hand too many interrupts can cause the Host to miss deadlines required for the application. Therefore the CC supports enable / disable controls for each individual interrupt source separately.

An interrupt may be triggered when

- An error was detected
- A status flag is set
- A timer reaches a preconfigured value
- A message transfer from Input Buffer to Message RAM or from Message RAM to Output Buffer has completed
- A stop watch event occurred

Tracking status and generating interrupts when a status change or an error occurs are two independent tasks. Regardless of whether an interrupt is enabled or not, the corresponding status is tracked and indicated by the CC. The Host has access to the actual status and error information by reading registers EIR and SIR.

Register	Bit	Function
	PEMC	Protocol Error Mode Changed
	CNA	Command Not Valid
	SFBM	Sync Frames Below Minimum
	SFO	Sync Frame Overflow
	CCF	Clock Correction Failure
	CCL	CHI Command Locked
	PERR	Parity Error
	RFO	Receive FIFO Overrun
EIR	EFA	Empty FIFO Access
LIK	IIBA	Illegal Input Buffer Access
	IOBA	Illegal Output Buffer Access
	MHF	Message Handler Constraints Flag
	EDA	Error Detected on Channel A
	LTVA	Latest Transmit Violation Channel A
	ТАВА	Transmission Across Boundary Channel A
	EDB	Error Detected on Channel B
	LTVB	Latest Transmit Violation Channel B
	TABB	Transmission Across Boundary Channel B

Register	Bit	Function
	WST	Wakeup Status
	CAS	Collision Avoidance Symbol
	CYCS	Cycle Start Interrupt
	TXI	Transmit Interrupt
	RXI	Receive Interrupt
	RFNE	Receive FIFO not Empty
	RFCL	Receive FIFO Critical Level
	NMVC	Network Management Vector Changed
	TIO	Timer Interrupt 0
SIR	TI1	Timer Interrupt 1
	TIBC	Transfer Input Buffer Completed
	TOBC	Transfer Output Buffer Completed
	SWE	Stop Watch Event
	SUCS	Startup Completed Successfully
	MBSI	Message Buffer Status Interrupt
	SDS	Start of Dynamic Segment
	WUPA	Wakeup Pattern Channel A
	MTSA	MTS Received on Channel A
	WUPB	Wakeup Pattern Channel B
	MTSB	MTS Received on Channel B
ILE	EINT0	Enable Interrupt Line 0
	EINT1	Enable Interrupt Line 1

#### Table 19: Module interrupt flags and interrupt line enable

The interrupt lines to the Host, **eray\_int0** and **eray\_int1**, are controlled by the enabled interrupts. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit **ILE.EINT0** and **ILE.EINT1**.

The two timer interrupts generated by interrupt timer 0 and 1 are available on pins **eray\_tint0** and **eray\_tint1**. They can be configured via registers TOC and T1C.

A stop watch event may be triggered via input pin **eray\_stpwt**.

The status of the data transfer between IBF / OBF and the Message RAM is signalled on pins **eray\_ibusy** and **eray\_obusy**. When a transfer has completed bit **SIR.TIBC** or **SIR.TOBC** is set.

# 6.2 Assignment of FlexRay Configuration Parameters

Parameter	Bit(field)	Page
pKeySlotusedForStartup	SUCC1.TXST	40
pKeySlotUsedForSync	SUCC1.TXSY	40
gColdStartAttempts	SUCC1.CSA[4:0]	40
pAllowPassiveToActive	SUCC1.PTA[4:0]	40
pWakeupChannel	SUCC1.WUCS	40
pSingleSlotEnabled	SUCC1.TSM	40
pAllowHaltDueToClock	SUCC1.HCSE	40
pChannels	SUCC1.CCHA SUCC1.CCHB	40
pdListenTimeOut	SUCC2.LT[20:0]	45
gListenNoise	SUCC2.LTN[3:0]	45
gMaxWithoutClockCorrectionPassive	SUCC3.WCP[3:0]	45
gMaxWithoutClockCorrectionFatal	SUCC3.WCF[3:0]	45
gNetworkManagementVectorLength	NEMC.NML[3:0]	46
gdTSSTransmitter	PRTC1.TSST[3:0]	47
gdCASRxLowMax	PRTC1.CASM[6:0]	47
gdSampleClockPeriod	PRTC1.BRP[1:0]	47
pSamplesPerMicrotick	PRTC1.BRP[1:0]	47
gdWakeupSymbolRxWindow	PRTC1.RXW[8:0]	47
pWakeupPattern	PRTC1.RWP[5:0]	47
gdWakeupSymbolRxIdle	PRTC2.RXI[5:0]	48
gdWakeupSymbolRxLow	PRTC2.RXL[5:0]	48
gdWakeupSymbolTxIdle	PRTC2.TXI[7:0]	48
gdWakeupSymbolTxLow	PRTC2.TXL[5:0]	48
gPayloadLengthStatic	MHDC.SFDL[6:0]	49
pLatestTx	MHDC.SLT[12:0]	49
pMicroPerCycle	GTUC1.UT[19:0]	50
gMacroPerCycle	GTUC2.MPC[13:0]	50
gSyncNodeMax	GTUC2.SNM[3:0]	50
pMicroInitialOffset[A]	GTUC3.UIOA[7:0]	51
pMicroInitialOffset[B]	GTUC3.UIOB[7:0]	51
pMacroInitialOffset[A]	GTUC3.MIOA[6:0]	51
pMacroInitialOffset[B]	GTUC3.MIOB[6:0]	51
gdNIT	GTUC4.NIT[13:0]	52
gOffsetCorrectionStart	GTUC4.OCS[13.0]	52

Parameter	Bit(field)	Page
pDelayCompensation[A]	GTUC5.DCA[7:0]	53
pDelayCompensation[B]	GTUC5.DCB[7:0]	53
pClusterDriftDamping	GTUC5.CDD[4:0]	53
pDecodingCorrection	GTUC5.DEC[7:0]	53
pdAcceptedStartupRange	GTUC6.ASR[10:0]	53
pdMaxDrift	GTUC6.MOD[10:0]	53
gdStaticSlot	GTUC7.SSL[9:0]	54
gNumberOfStaticSlots	GTUC7.NSS[9:0]	54
gdMinislot	GTUC8.MSL[5:0]	54
gNumberOfMinislots	GTUC8.NMS[12:0]	54
gdActionPointOffset	GTUC9.APO[5:0]	55
gdMinislotActionPoint	GTUC9.MAPO[4:0]	55
gdDynamicSlotIdlePhase	GTUC9.DSI[1:0]	55
pOffsetCorrectionOut	GTUC10.MOC[13:0]	55
pRateCorrectionOut	GTUC10.MRC[10:0]	55
pExternOffsetCorrection	GTUC11.EOC[2:0]	56
pExternRateCorrection	GTUC11.ERC[2:0]	56

#### Table 21: FlexRay configuration parameters

## E-Ray

# List of Figures

Figure 1: E-Ray block diagram 15
Figure 2: Structure of communication cycle    98
Figure 3: Configuration of NIT start and offset correction start
Figure 4: Overall state diagram of E-Ray communication controller 106
Figure 5: Structure of POC state WAKEUP 111
Figure 6: Timing of wakeup pattern 113
Figure 7: State diagram time-triggered startup         115
Figure 8: FIFO status: empty, not empty, overrun
Figure 9: Host access to Message RAM 133
Figure 10: Double buffer structure Input Buffer
Figure 11: Swapping of IBCM and IBCR bits 134
Figure 12: Double buffer structure Output Buffer
Figure 13: Swapping of OBCM and OBCR bits 136
Figure 14: Access to Transient Buffer RAMs 139
Figure 15: Configuration example of message buffers in the Message RAM 140
Figure 16: Parity generation and check 145
