

6-Bit Universal Up/Down Counter

The MC10E/100E136 is a 6-bit synchronous, presettable, cascadable universal counter. The device generates a look-ahead-carry output and accepts a look-ahead-carry input. These two features allow for the cascading of multiple E136's for wider bit width counters that operate at very nearly the same frequency as the stand alone counter.

- 550 MHz Count Frequency
- Fully Synchronous Up and Down Counting
- Internal 75 k Ω Input Pulldown Resistors
- Look-Ahead-Carry Input and Output
- Asynchronous Master Reset
- Extended 100E V_{EE} Range of -4.2 V to -5.46 V

The CLOUT output will pulse LOW for one clock cycle one count before the E136 reaches terminal count. The COUT output will pulse LOW for one clock cycle when the counter reaches terminal count. For more information on utilizing the look-ahead-carry features of the device please refer to the applications section of this data sheet. The differential COUT output facilitates the E136's use in programmable divider and self-stopping counter applications.

Unlike the H136 and other similar universal counter designs the E136 carry out and look-ahead-carry out signals are registered on chip. This design alleviates the glitch problem seen on many counters where the carry out signals are merely gated. Because of this architecture there are some minor functional differences between the E136 and H136 counters. The user, regardless of familiarity with the H136, should read this data sheet carefully. Note specifically (see logic diagram) the operation of the carry out outputs and the look-ahead-carry in input when utilizing the master reset.

When left open all of the input pins will be pulled LOW via an input pulldown resistor. The master reset is an asynchronous signal which when asserted will force the Q outputs LOW.

The Q outputs need not be terminated for the E136 to function properly, in fact if these outputs will not be used in a system it is recommended to save power and minimize noise that they be left open. This practice will minimize switching noise which can reduce the maximum count frequency of the device or significantly reduce margins against other noise in the system.

Z = Low to High Transition

Figure 2. Look-Ahead-Carry Input Structure

Note from the waveforms that the look-ahead-carry output (CLOUT) pulses low one clock pulse before the counter reaches terminal count. Also note that both CLOUT and the carry out pin (COUT) of the device pulse low for only one clock period. The input structure for look-ahead-carry in (CLIN) and carry in (CIN) is pictured in Figure 2.

The CLIN input is registered and then ORed with the CIN input. From the truth table one can see that both the CIN and the CLIN inputs must be in a LOW state for the E136 to be enabled to count (either count up or count down). The CLIN inputs are driven by the CLOUT output of the lowest order E136 and therefore are only asserted for a single clock period. Since the CLIN input is registered it must be asserted one clock period prior to the CIN input.

If the counter previous to a given counter is at terminal count its COUT output and thus the CIN input of the given counter will be in the "LOW" state. This signals the given counter that it will need to count one upon the next terminal count of the least significant counter (LSC). The CLOUT output of the LSC will pulse low one clock period before it reaches terminal count. This CLOUT signal will be clocked into the CLIN input of the higher order counters on the following positive clock transition. Since both CIN and CLIN are in the LOW state the next clock pulse will cause the least significant counter to roll over and all higher order counters, if signaled by their CIN inputs, to count by one.

Figure 3. 6-bit Programmable Divider

During the clock pulse in which the higher order counter is counting by one the CLIN is clocking in the high signal presented by the CLOUT of the LSC. The CIN's in the higher order counter will ripple propagate through the chain to update the count status for the next occurrence of terminal count on the LSC. This ripple propagation will not affect the count frequency as it has 2^6-1 or 63 clock pulses to ripple through without affecting the count operation of the chain.

The only limiting factor which could reduce the count frequency of the chain as compared to a free running single device will be the setup time of the CLIN input. This limit will consist of the CLK to CLOUT delay of the E136 plus the CLIN setup time plus any path length differences between the CLOUT output and the clock.

Programmable Divider

Using external feedback of the COUT pin, the E136 can be configured as a programmable divider. Figure 3 illustrates the configuration for a 6-bit count down programmable divider. If for some reason a count up divider is preferred the COUT signal is simply fed back to S2 rather than S1. Examination of the truth table for the E136 shows that when both S1 and S2 are LOW the counter will parallel load on the next positive transition of the clock. If the S2 input is low and the S1 input is high the counter will be in the count down mode and will count towards an all zero state upon successive clock pulses. Knowing this and the operation of the COUT output it becomes a trivial matter to build programmable dividers.

For a programmable divider one wants to load a predesignated number into the counter and count to terminal count. Upon terminal count the counter should automatically reload the divide number. With the architecture shown in Figure 3 when the counter reaches terminal count the COUT output and thus the S1 input will go LOW, this combined with the low on S2 will cause the counter to load the inputs present on D0-D5. Upon loading the divide value into the counter COUT will go HIGH as the counter is no longer at terminal count thereby placing the counter back into the count mode.

Figure 4. Programmable Divider Waveforms

The exercise of building a programmable divider then becomes simply determining what value to load into the counter to accomplish the desired division. Since the load operation requires a clock pulse, to divide by N , $N-1$ must be loaded into the counter. A single E136 device is capable of divide ratios of 2 to 64 inclusive, Table 1 outlines the load values for the various divide ratios. Figure 4 presents the waveforms resulting from a divide by 37 operation. Note that the availability of the COUT complementary output $\overline{\text{COUT}}$ allows the user to choose the polarity of the divide by output.

For single device programmable counters the E016 counter is probably a better choice than the E136. The E016 has an internal feedback to control the reloading of the counter, this not only simplifies board design but also will result in a faster maximum count frequency.

For programmable dividers of larger than 8 bits the

superiority of the E016 diminishes, and in fact for very wide dividers the E136 will provide the capability of a faster count frequency. This potential is a result of the cascading features mentioned previously in this document. Figure 5 shows the architecture of a 24-bit programmable divider implemented using E136 counters. Note the need for one external gate to control the loading of the entire counter chain. An ideal device for the external gating of this architecture would be the 4-input OR function in the 8-lead SOIC ECLinPS Lite™ family. However the final decision as to what device to use for the external gating requires a balancing of performance needs, cost and available board space. Note that because of the need for external gating the maximum count frequency of a given sized programmable divider will be less than that of a single cascaded counter.
