National Semiconductor

# LM7171 Very High Speed, High Output Current, Voltage **Feedback Amplifier**

# **General Description**

The LM7171 is a high speed voltage feedback amplifier that has the slewing characteristic of a current feedback amplifier; yet it can be used in all traditional voltage feedback amplifier configurations. The LM7171 is stable for gains as low as +2 or -1. It provides a very high slew rate at 4100V/µs and a wide unity-gain bandwidth of 200 MHz while consuming only 6.5 mA of supply current. It is ideal for video and high speed signal processing applications such as HDSL and pulse amplifiers. With 100 mA output current, the LM7171 can be used for video distribution, as a transformer driver or as a laser diode driver.

Operation on ±15V power supplies allows for large signal swings and provides greater dynamic range and signal-to-noise ratio. The LM7171 offers low SFDR and THD, ideal for ADC/DAC systems. In addition, the LM7171 is specified for ±5V operation for portable applications.

The LM7171 is built on National's advanced VIP™ III (Vertically integrated PNP) complementary bipolar process.

# Features

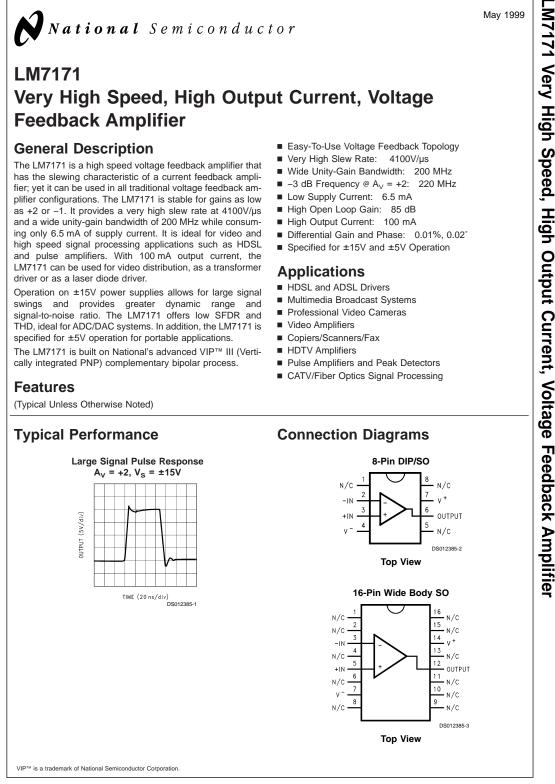

(Typical Unless Otherwise Noted)

Easy-To-Use Voltage Feedback Topology

- Very High Slew Rate: 4100V/µs
- Wide Unity-Gain Bandwidth: 200 MHz
- -3 dB Frequency @ A<sub>V</sub> = +2: 220 MHz
- Low Supply Current: 6.5 mA
- High Open Loop Gain: 85 dB
- High Output Current: 100 mA
- Differential Gain and Phase: 0.01%, 0.02°
- Specified for ±15V and ±5V Operation

#### Applications

- HDSL and ADSL Drivers
- Multimedia Broadcast Systems
- Professional Video Cameras
- Video Amplifiers
- Copiers/Scanners/Fax
- HDTV Amplifiers
- Pulse Amplifiers and Peak Detectors CATV/Fiber Optics Signal Processing

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not guaranteed. For guaranteed specifications and the test conditions, see the Electrical Characteristics. Note 2: Human body model, 1.5 kΩ in series with 100 pF.

Note 3: Applies to both single-supply and split-supply operation. Continuous short circuit operation at elevated ambient temperature can result in exceeding the maximum allowed junction temperature of 150°C.

Note 4: The maximum power dissipation is a function of  $T_{J(max)}$ ,  $\theta_{JA}$ , and  $T_A$ . The maximum allowable power dissipation at any ambient temperature is  $P_D = (T_{J(max)} - T_A)/\theta_{JA}$ . All numbers apply for packages soldered directly into a PC board.

Note 5: Typifcal values represent the most likely parametric norm.

.

Note 6: All limits are guaranteed by testing or statistical analysis.

Note 7: Large signal voltage gain is the total output swing divided by the input signal required to produce that swing. For  $V_S = \pm 15V$ ,  $V_{OUT} = \pm 5V$ . For  $V_S = \pm 5V$ ,  $V_{OUT} = \pm 1V$ .

Note 8: The open loop output current is guaranteed, by the measurement of the open loop output voltage swing, using 1000 output load.

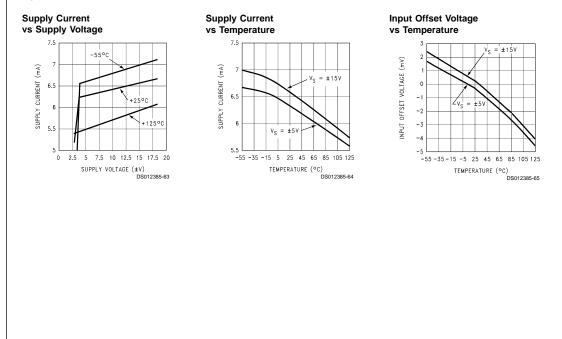

Note 9: Slew Rate is the average of the raising and falling slew rates.

Note 10: Differential gain and phase are measured with  $A_V$  = +2,  $V_{IN}$  = 1  $V_{PP}$  at 3.58 MHz and both input and output 75 $\Omega$  terminated.

Note 11: Input differential voltage is applied at  $V_S = \pm 15V$ .

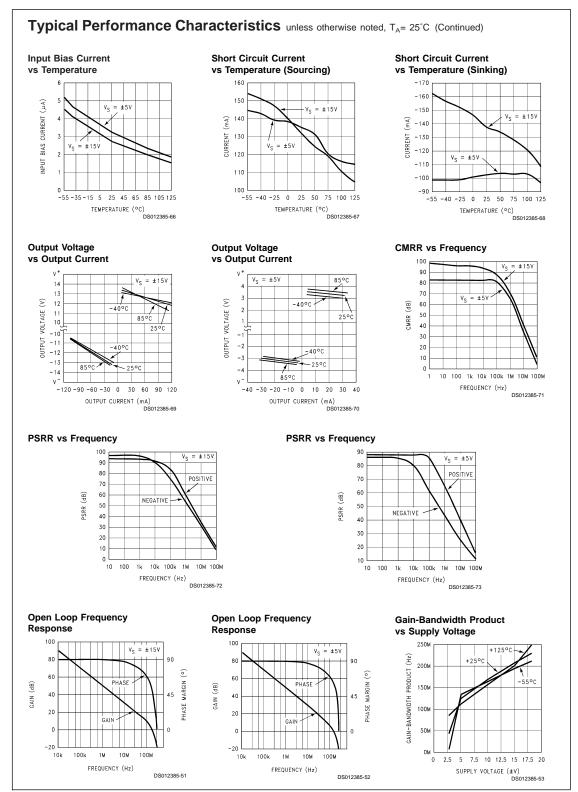

Note 12: Harmonics are measured with V\_{IN} = 1 V\_{PP}, A\_V = +2 and R\_L = 100 $\Omega$ .

#### **Application Notes**

# LM7171 Performance Discussion

The LM7171 is a very high speed, voltage feedback amplifier. It consumes only 6.5 mA supply current while providing a unity-gain bandwidth of 200 MHz and a slew rate of 4100V/  $\mu$ s. It also has other great features such as low differential gain and phase and high output current.

The LM7171 is a true voltage feedback amplifier. Unlike current feedback amplifiers (CFAs) with a low inverting input impedance and a high non-inverting input impedance, both inputs of voltage feedback amplifiers (VFAs) have high impedance nodes. The low impedance inverting input in CFAs and a feedback capacitor create an additional pole that will lead to instability. As a result, CFAs cannot be used in traditional op amp circuits such as photodiode amplifiers, I-to-V converters and integrators where a feedback capacitor is required.

# LM7171 Circuit Operation

The class AB input stage in LM7171 is fully symmetrical and has a similar slewing characteristic to the current feedback amplifiers. In the LM7171 Simplified Schematic, Q1 through Q4 form the equivalent of the current feedback input buffer,  $R_{\rm E}$  the equivalent of the feedback resistor, and stage A buff-

#### LM7171 Circuit Operation (Continued)

ers the inverting input. The triple-buffered output stage isolates the gain stage from the load to provide low output impedance.

# LM7171 Slew Rate Characteristic

The slew rate of LM7171 is determined by the current available to charge and discharge an internal high impedance node capacitor. This current is the differential input voltage divided by the total degeneration resistor  $R_{\rm E}$ . Therefore, the slew rate is proportional to the input voltage level, and the higher slew rates are achievable in the lower gain configurations. A curve of slew rate versus input voltage level is provided in the "Typical Performance Characteristics".

When a very fast large signal pulse is applied to the input of an amplifier, some overshoot or undershoot occurs. By placing an external resistor such as 1 k $\Omega$  in series with the input of LM7171, the bandwidth is reduced to help lower the overshoot.

### **Slew Rate Limitation**

If the amplifier's input signal has too large of an amplitude at too high of a frequency, the amplifier is said to be slew rate limited; this can cause ringing in time domain and peaking in frequency domain at the output of the amplifier.

In the "Typical Performance Characteristics" section, there are several curves of  $A_V = +2$  and  $A_V = +4$  versus input signal levels. For the  $A_V = +4$  curves, no peaking is present and the LM7171 responds identically to the different input signal levels of 30 mV, 100 mV and 300 mV.

For the  $A_{\vee}$  = +2 curves, with slight peaking occurs. This peaking at high frequency (>100 MHz) is caused by a large input signal at high enough frequency that exceeds the amplifier's slew rate. The peaking in frequency response does not limit the pulse response in time domain, and the LM7171 is stable with noise gain of ≥+2.

# Layout Consideration

# PRINTED CIRCUIT BOARDS AND HIGH SPEED OP AMPS

There are many things to consider when designing PC boards for high speed op amps. Without proper caution, it is very easy to have excessive ringing, oscillation and other degraded AC performance in high speed circuits. As a rule, the signal traces should be short and wide to provide low inductance and low impedance paths. Any unused board space needs to be grounded to reduce stray signal pickup. Critical components should also be grounded at a common point to eliminate voltage drop. Sockets add capacitance to the board and can affect high frequency performance. It is better to solder the amplifier directly into the PC board without using any socket.

#### **USING PROBES**

Active (FET) probes are ideal for taking high frequency measurements because they have wide bandwidth, high input impedance and low input capacitance. However, the probe ground leads provide a long ground loop that will produce errors in measurement. Instead, the probes can be grounded directly by removing the ground leads and probe jackets and using scope probe jacks.

#### COMPONENT SELECTION AND FEEDBACK RESISTOR

It is important in high speed applications to keep all component leads short. For discrete components, choose carbon composition-type resistors and mica-type capacitors. Surface mount components are preferred over discrete components for minimum inductive effect.

Large values of feedback resistors can couple with parasitic capacitance and cause undesirable effects such as ringing or oscillation in high speed amplifiers. For LM7171, a feedback resistor of  $510\Omega$  gives optimal performance.

## Compensation for Input Capacitance

The combination of an amplifier's input capacitance with the gain setting resistors adds a pole that can cause peaking or oscillation. To solve this problem, a feedback capacitor with a value

$$C_F > (R_G \times C_{IN})/R_F$$

can be used to cancel that pole. For LM7171, a feedback capacitor of 2 pF is recommended. *Figure 1* illustrates the compensation circuit.

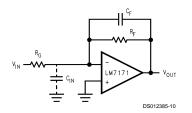

FIGURE 1. Compensating for Input Capacitance

### Power Supply Bypassing

Bypassing the power supply is necessary to maintain low power supply impedance across frequency. Both positive and negative power supplies should be bypassed individually by placing 0.01  $\mu F$  ceramic capacitors directly to power supply pins and 2.2  $\mu F$  tantalum capacitors close to the power supply pins.

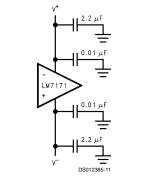

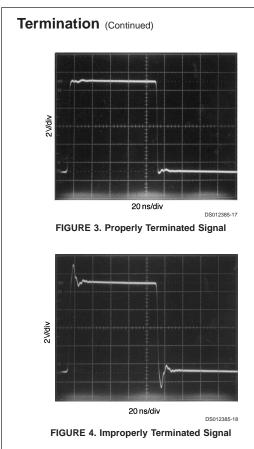

FIGURE 2. Power Supply Bypassing

#### Termination

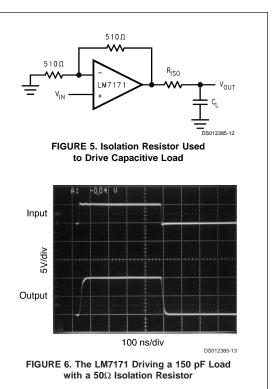

In high frequency applications, reflections occur if signals are not properly terminated. *Figure 3* shows a properly terminated signal while *Figure 4* shows an improperly terminated signal.

To minimize reflection, coaxial cable with matching characteristic impedance to the signal source should be used. The other end of the cable should be terminated with the same value terminator or resistor. For the commonly used cables, RG59 has  $75\Omega$  characteristic impedance, and RG58 has  $50\Omega$  characteristic impedance.

# **Driving Capacitive Loads**

Amplifiers driving capacitive loads can oscillate or have ringing at the output. To eliminate oscillation or reduce ringing, an isolation resistor can be placed as shown below in *Figure* 5 The combination of the isolation resistor and the load capacitor forms a pole to increase stability by adding more phase margin to the overall system. The desired performance depends on the value of the isolation resistor; the bigger the isolation resistor, the more damped the pulse response becomes. For LM7171, a 50 $\Omega$  isolation resistor is recommended for initial evaluation. *Figure* 6 shows the LM7171 driving a 150 pF load with the 50 $\Omega$  isolation resistor.

#### Power Dissipation

The maximum power allowed to dissipate in a device is defined as:

 $P_{D} = (T_{J(max)} - T_{A})/\theta_{JA}$ 

Where

PD is the power dissipation in a device

 $T_{J(max)}$  is the maximum junction temperature

 $T_A$  is the ambient temperature

 $\theta_{JA} \qquad \mbox{is the thermal resistance of a particular package} \\ For example, for the LM7171 in a SO-8 package, the maximum power dissipation at 25°C ambient temperature is 730 mW.$ 

Thermal resistance,  $\theta_{JA}$ , depends on parameters such as die size, package size and package material. The smaller the die size and package, the higher  $\theta_{JA}$  becomes. The 8-pin DIP package has a lower thermal resistance (108°C/W) than that of 8-pin SO (172°C/W). Therefore, for higher dissipation capability, use an 8-pin DIP package.

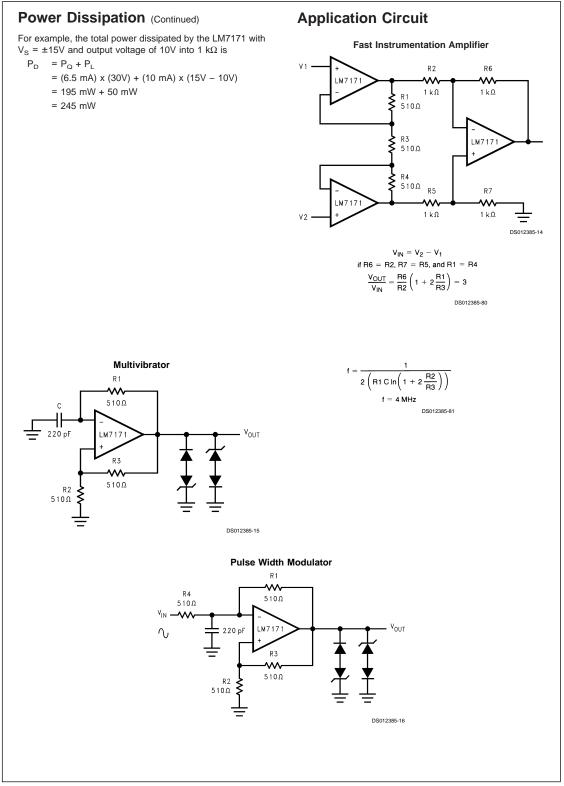

The total power dissipated in a device can be calculated as:

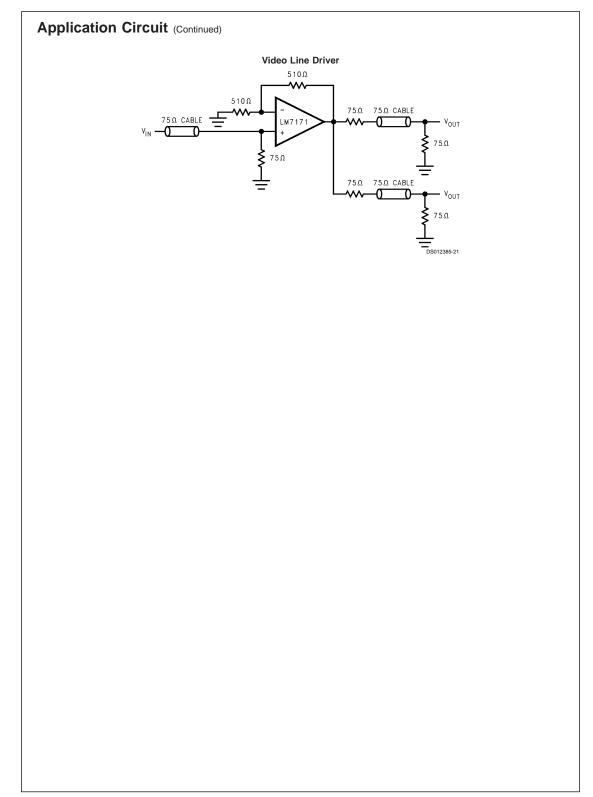

$$P_D = P_Q + P_I$$

 $\mathsf{P}_\mathsf{Q}$  is the quiescent power dissipated in a device with no load connected at the output.  $\mathsf{P}_\mathsf{L}$  is the power dissipated in the device with a load connected at the output; it is not the power dissipated by the load.

Furthermore,

- $P_Q$ : = supply current x total supply voltage with no load
- P<sub>L</sub>: = output current x (voltage difference between supply voltage and output voltage of the same side of supply voltage)

# **Design Kit**

A design kit is available for the LM7171. The design kit contains:

- High Speed Evaluation Board
- LM7171 in 8-pin DIP Package
- LM7171 Datasheet
- Pspice Macromodel DIskette With The LM7171 Macromodel
- Amplifier Selection Guide

#### **Pitch Pack**

A pitch pack is available for the LM7171. The pitch pack contains:

- LM7171 in 8-pin DIP Package
- LM7171 Datasheet
- Pspice Macromodel DIskette With The LM7171 Macromodel
- Amplifier Selection Guide

Contact your local National Semiconductor sales office to obtain a pitch pack and design kit.
