LM6118/LM6218 Fast Settling Dual Operational Amplifiers

General Description

The LM6118/LM6218 are monolithic fast-settling unity-gain-compensated dual operational amplifiers with ± 20 mA output drive capability. The PNP input stage has a typical bias current of 200 nA, and the operating supply voltage is $\pm 5 \text{V}$ to $\pm 20 \text{V}$.

These dual op amps use slew enhancement with special mirror circuitry to achieve fast response and high gain with low total supply current.

The amplifiers are built on a junction-isolated VIP $^{\text{TM}}$ (Vertically Integrated PNP) process which produces fast PNP's that complement the standard NPN's.

Features

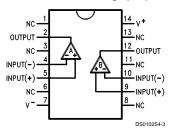

■ Low offset voltage:	0.2 m\
■ 0.01% settling time:	400 ns
■ Slew rate A _v = -1:	140 V/µs
■ Slew rate A _v = +1:	75 V/µs
■ Gain bandwidth:	17 MH
■ Total supply current:	5.5 mA
■ Output drives 50Ω load (±1V)	

Applications

- D/A converters
- Fast integrators
- Active filters

	Follower	3				pF

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its rated operating conditions.

Note 2: Input voltage range is $(V^+ - 1V)$ to (V^-) .

Electrical Characteristics (Continued)

Note 3: The inputs are shunted with three series-connected diodes back-to-back for input differential clamping. Therefore differential input voltages greater than about 1.8V will cause excessive current to flow unless limited to less than 10 mA.

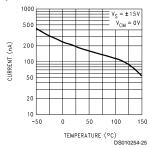

Note 4: Current limiting protects the output from a short to ground or any voltage less than the supplies. With a continuous overload, the package dissipation must be taken into account and heat sinking provided when necessary.

Note 5: Devices must be derated using a thermal resistance of 90°C/W for the N and WM packages.

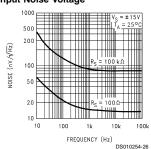

Note 6: Limits are guaranteed by testing or correlation.

Application Information

General

The LM6118/LM6218 are high-speed, fast-settling dual op-amps. To insure maximum performance, circuit board layout is very important. Minimizing stray capacitance at the inputs and reducing coupling between the amplifier's input and output will minimize problems.

Supply Bypassing

To assure stability, it is recommended that each power supply pin be bypassed with a 0.1 μF low inductance capacitor near the device. If high frequency spikes from digital circuits or switching supplies are present, additional filtering is recommended. To prevent these spikes from appearing at the output, R-C filtering of the supplies near the device may be necessary.

Power Dissipation

These amplifiers are specified to 20 mA output current. If accompanied with high supply voltages, relatively high power dissipation in the device will occur, resulting in high junction temperatures. In these cases the package thermal resistance must be taken into consideration. (See Note 5 under Electrical Characteristics.) For high dissipation, an N package with large areas of copper on the pc board is recommended.

Amplifier Shut Down

If one of the amplifiers is not used, it can be shut down by connecting both the inverting and non-inverting inputs to the V– pin. This will reduce the power supply current by approximately 25%.

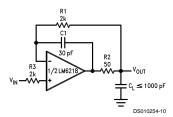

Capacitive Loading

Maximum capacitive loading is about 50 pF for a closed-loop gain of +1, before the amplifier exhibits excessive ringing and becomes unstable. A curve showing maximum capacitive loads, with different closed-loop gains, is shown in the Typical Performance Characteristics section.

To drive larger capacitive loads at low closed-loop gains, isolate the amplifier output from the capacitive load with 50Ω . Connect a small capacitor directly from the amplifier output to the inverting input. The feedback loop is closed from the isolated output with a series resistor to the inverting input.

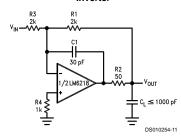

Application Information (Continued)

Voltage Follower

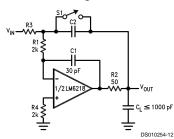

For C_L = 1000 pF, Small signal BW = 5 MHz 20 V_{p-p} BW = 500 kHz

Inverter

Settling time to 0.01%, 10V Step For C_L = 1000 pF, settling time \approx 1500 ns For C_L = 300 pF, settling time \approx 500 ns

Integrator

Examples of unity gain connections for a voltage follower, Inverter, and integrator driving capacitive loads up to 1000 pF are shown here. Different R1–C1 time constants and capacitive loads will have an effect on settling times.

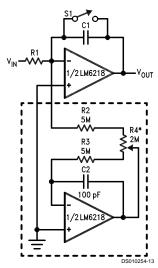

Input Bias Current Compensation

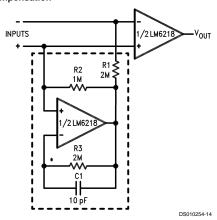

Input bias current of the first op amp can be reduced or balanced out by the second op amp. Both amplifiers are laid out in mirror image fashion and in close proximity to each other, thus both input bias currents will be nearly identical and will track with temperature. With both op amp inputs at the same potential, a second op amp can be used to convert bias current to voltage, and then back to current feeding the first op amp using large value resistors to reduce the bias current to the level of the offset current.

Examples are shown here for an inverting application, (a) where the inputs are at ground potential, and a second circuit (b) for compensating bias currents for both inputs.

Application Information (Continued)

Bias Current Compensation

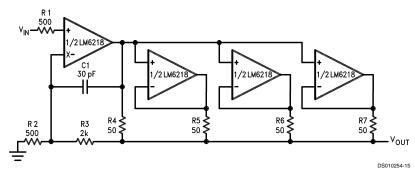

*mount resistor close to input pin to minimize stray capacitance

(b) Compensation to Both Inputs

*adjust for zero integrator drift

(a) Inverting Input Bias Compensation for Integrator Application

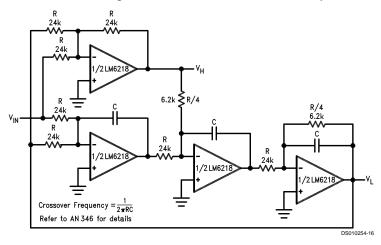

Amplifier/Parallel Buffer

 A_V = +5, I_{OUT} \leq 80 mA V_S = ±15V, $C_L \leq$ 0.01 μF Large and small signal B.W. = 1.3 MHz (THD = 3%)

Application Information (Continued)

Constant-Voltage Crossover Network With 12 dB/Octave Slope

Bilateral Current Source

 $V_S = \pm 15V$, $-10 \le V_{IN} \le 10V$

$$\frac{I_{OUT}}{V_{IN}} = \frac{R4}{R2 R6} = \frac{1 mA}{1V}$$

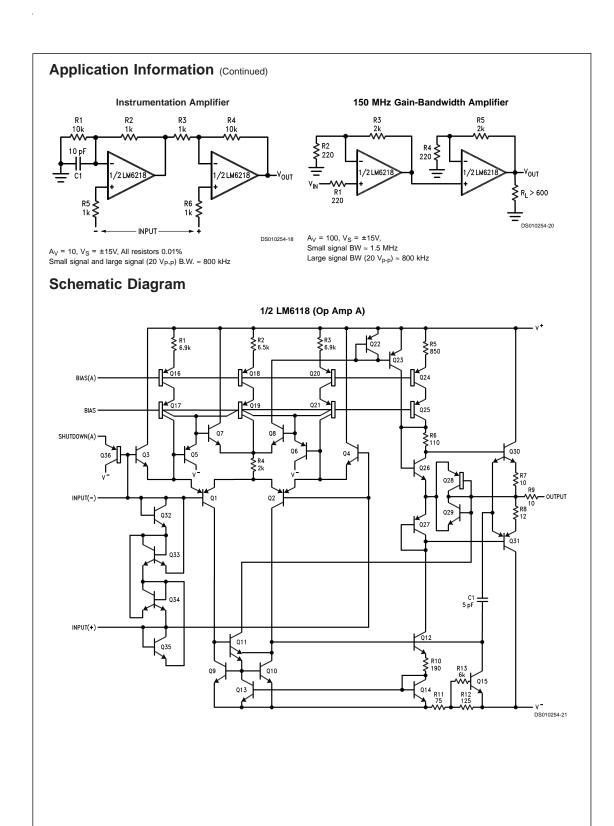

Output dynamic range = 10V - R6 $|I_{OUT}|$ R_L = 500 Ω , small signal BW = 6 MHz Large signal response = 800 kHz

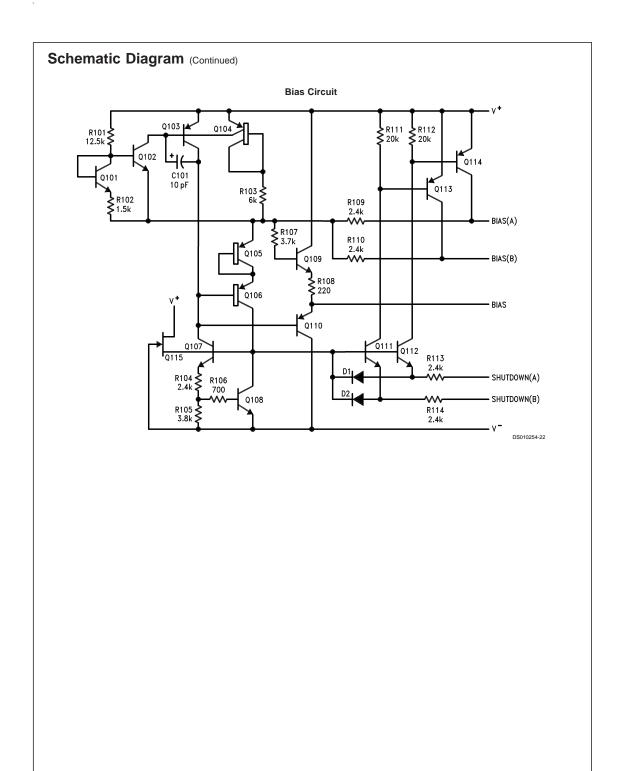

$$C_{out}$$
 equiv. = $\frac{R2 + R4}{2\pi f_0 R2 R6} = 32 pF (f_0 = 15 MHz)$

Coaxial Cable Driver

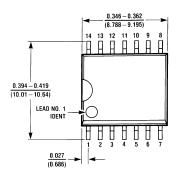

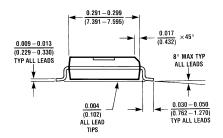

Small signal (200 mV $_{p\text{-}p})$ BW ≈ 5 MHz
