

## NM27P512

### 524,288-Bit (64K x 8) Processor Oriented CMOS EPROM

#### General Description

The NM27P512 is a 512K Processor Oriented EPROM configured as 64k x 8. It's designed to simplify microprocessor interfacing while remaining compatible with standard EPROMs. It can reduce both wait states and glue logic when the specification improvements are taken advantage of in the system design. The NM27P512 is implemented in National's advanced CMOS EPROM process to provide excellent reliability and access times as fast as 120 ns.

The interface improvements address two areas to eliminate the need for additional devices to adapt the EPROM to the microprocessor and to eliminate wait states at the termination of the access cycle. Even with these improvements, the NM27P512 remains compatible with industry standard JEDEC pinout EPROMs. The maximum specification for output turn-off time has been reduced, eliminating the need for wait states at the end of a read cycle. Also, the minimum specification for output hold time has been increased, eliminating the need for external circuitry to hold the data.

#### Features

- Fast output turn off to eliminate wait states
- Extended data hold time for microprocessor compatibility
- High performance CMOS
  - 120 ns access time
- JEDEC standard pin configuration
- Manufacturer's identification code

## Capacitance $T_A = +25^\circ\text{C}$ , $f = 1\text{ MHz}$ (Note 2)

Symbol	Parameter	Conditions	Typ	Max	Units
$C_{IN1}$	Input Capacitance except $\overline{OE}/V_{PP}$	$V_{IN} = 0\text{V}$	6	12	pF
$C_{OUT}$	Output Capacitance	$V_{OUT} = 0\text{V}$	9	12	pF
$C_{IN2}$	$\overline{OE}/V_{PP}$ Input Capacitance	$V_{IN} = 0\text{V}$	20	25	pF

## AC Test Conditions

Output Load	1 TTL Gate and $C_L = 100\text{ pF}$ (Note 8)	Timing Measurement Reference Level (Note 9)	
Input Rise and Fall Times	$\leq 5\text{ ns}$	Inputs	0.8V and 2V
Input Pulse Levels	0.45V to 2.4V	Outputs	0.8V and 2V

## AC Waveforms (Notes 6, 7)

TL/D/11365-4

**Note 1:** Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**Note 2:** This parameter is only sampled and is not 100% tested.

**Note 3:**  $\overline{OE}$  may be delayed up to  $t_{ACC} - t_{OE}$  after the falling edge of  $\overline{CE}$  without impacting  $t_{ACC}$ .

**Note 4:** The  $t_{DF}$  and  $t_{CF}$  compare level is determined as follows:

- High to TRI-STATE, the measured  $V_{OH1}$  (DC) - 0.10V;
- Low to TRI-STATE, the measured  $V_{OL1}$  (DC) + 0.10V.

**Note 5:** TRI-STATE may be attained using  $\overline{OE}$  or  $\overline{CE}$ .

**Note 6:** The power switching characteristics of EPROMs require careful device decoupling. It is recommended that at least a 0.1  $\mu\text{F}$  ceramic capacitor be used on every device between  $V_{CC}$  and GND.

**Note 7:** The outputs must be restricted to  $V_{CC} + 1.0\text{V}$  to avoid latch-up and device damage.

**Note 8:** 1 TTL Gate:  $I_{OL} = 1.6\text{ mA}$ ,  $I_{OH} = -400\text{ }\mu\text{A}$ .  
 $C_L$ : 100 pF includes fixture capacitance.

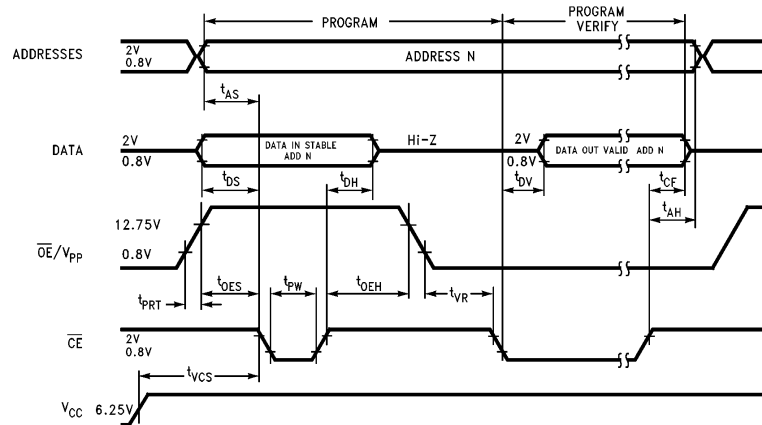

**Note 9:** Inputs and outputs can undershoot to  $-2.0\text{V}$  for 20 ns Max.

**Note 10:** CMOS inputs;  $V_{IL} = \text{GND} \pm 0.3\text{V}$ ,  $V_{IH} = V_{CC} \pm 0.3\text{V}$ .

## Programming Characteristics (Notes 1 and 2)

## Programming Waveforms

TL/D/11365-5

**Note 1:** National's standard product warranty applies to devices programmed to specifications described herein.

**Note 2:**  $V_{CC}$  must be applied simultaneously or before  $V_{PP}$  and removed simultaneously or after  $V_{PP}$ . The EPROM must not be inserted into or removed from a board with voltage applied to  $V_{PP}$  or  $V_{CC}$ .

**Note 3:** The maximum absolute allowable voltage which may be applied to the  $V_{PP}$  pin during programming is 14V. Care must be taken when switching the  $V_{PP}$  supply to prevent any overshoot from exceeding this 14V maximum specification. At least a 0.1  $\mu F$  capacitor is required across  $V_{CC}$  to GND to suppress spurious voltage transients which may damage the device.

**Note 4:** Programming and program verify are tested with the fast Program Algorithm at typical power supply voltages and timings.

## Fast Programming Algorithm Flow Chart

FIGURE 1

TL/D/11365-6

## Functional Description

### DEVICE OPERATION

The six modes of operation of the EPROM are listed in Table I. It should be noted that all inputs for the six modes are at TTL levels. The power supplies required are  $V_{CC}$  and  $OE/V_{PP}$ . The  $OE/V_{PP}$  power supply must be at 12.75V during the three programming modes, and must be at 5V in the other three modes. The  $V_{CC}$  power supply must be at 6.25V during the three programming modes, and at 5V in the other three modes.

#### Read Mode

The EPROM has two control functions, both of which must be logically active in order to obtain data at the outputs. Chip Enable ( $CE/PGM$ ) is the power control and should be used for device selection. Output Enable ( $OE/V_{PP}$ ) is the output control and should be used to gate data to the output pins, independent of device selection. Assuming that addresses are stable, address access time ( $t_{ACC}$ ) is equal to the delay from  $CE$  to output ( $t_{CE}$ ). Data is available at the outputs  $t_{OE}$  after the falling edge of  $OE$ , assuming that  $CE$  has been low and addresses have been stable for at least  $t_{ACC}-t_{OE}$ .

#### Standby Mode

The EPROM has a standby mode which reduces the active power dissipation by over 99%, from 385 mW to 0.55 mW. The EPROM is placed in the standby mode by applying a CMOS high signal to the  $CE/PGM$  input. When in standby mode, the outputs are in a high impedance state, independent of the  $OE$  input.

#### Output Disable

The EPROM is placed in output disable by applying a TTL high signal to the  $OE$  input. When in output disable all circuitry is enabled, except the outputs are in a high impedance state (TRI-STATE).

#### Output OR-Typing

Because the EPROM is usually used in larger memory arrays, National has provided a 2-line control function that accommodates this use of multiple memory connections. The 2-line control function allows for:

- a) the lowest possible memory power dissipation, and
- b) complete assurance that output bus contention will not occur.

To most efficiently use these two control lines, it is recommended that  $CE/PGM$  be decoded and used as the primary device selecting function, while  $OE/V_{PP}$  be made a common connection to all devices in the array and connected to the READ line from the system control bus.

This assures that all deselected memory devices are in their low power standby modes and that the output pins are active only when data is desired from a particular memory device.

### Programming

CAUTION: Exceeding 14V on pin 22 ( $OE/V_{PP}$ ) will damage the EPROM.

Initially, and after each erasure, all bits of the EPROM are in the "1's" state. Data is introduced by selectively programming "0's" into the desired bit locations. Although only "0's" will be programmed, both "1's" and "0's" can be presented in the data word. The only way to change a "0" to a "1" is by ultraviolet light erasure.

The EPROM is in the programming mode when the  $OE/V_{PP}$  is at 12.75V. It is required that at least a 0.1  $\mu F$  capacitor be placed across  $V_{CC}$  to ground to suppress spurious voltage transients which may damage the device. The data to be programmed is applied 8 bits in parallel to the data output pins. The levels required for the address and data inputs are TTL.

When the address and data are stable, an active low, TTL program pulse is applied to the  $CE/PGM$  input. A program pulse must be applied at each address location to be programmed.

The EPROM is programmed with the Fast Programming Algorithm shown in Figure 1. Each Address is programmed with a series of 100  $\mu s$  pulses until it verifies good, up to a maximum of 25 pulses. Most memory cells will program with a single 100  $\mu s$  pulse.

The EPROM must not be programmed with a DC signal applied to the  $CE/PGM$  input.

Programming multiple EPROM in parallel with the same data can be easily accomplished due to the simplicity of the programming requirements. Like inputs of the parallel EPROM may be connected together when they are programmed with the same data. A low level TTL pulse applied to the  $CE/PGM$  input programs the paralleled EPROM.

#### Program Inhibit

Programming multiple EPROMs in parallel with different data is also easily accomplished. Except for  $CE/PGM$  all like inputs (including  $OE/V_{PP}$ ) of the parallel EPROMs may be common. A TTL low level program pulse applied to an EPROM's  $CE/PGM$  input with  $OE/V_{PP}$  at 12.75V will program that EPROM. A TTL high level  $CE/PGM$  input inhibits the other EPROMs from being programmed.

## Functional Description (Continued)

### Program Verify

A verify should be performed on the programmed bits to determine whether they were correctly programmed. The verify is accomplished with OE/V<sub>PP</sub> and CE at V<sub>IL</sub>. Data should be verified T<sub>DV</sub> after the falling edge of CE.

### AFTER PROGRAMMING

Opaque labels should be placed over the EPROM window to prevent unintentional erasure. Covering the window will also prevent temporary functional failure due to the generation of photo currents.

### MANUFACTURER'S IDENTIFICATION CODE

The EPROM has a manufacturer's identification code to aid in programming. When the device is inserted in an EPROM programmer socket, the programmer reads the code and then automatically calls up the specific programming algorithm for the part. This automatic programming control is only possible with programmers which have the capability of reading the code.

The Manufacturer's Identification code, shown in Table II, specifically identifies the manufacturer and device type. The code for NM27P512 is "8F85", where "8F" designates that it is made by National Semiconductor, and "85" designates a 512K part.

The code is accessed by applying 12V  $\pm$  0.5V to address pin A9. Addresses A1–A8, A10–A16, and all control pins are held at V<sub>IL</sub>. Address pin A0 is held at V<sub>IL</sub> for the manufacturer's code, and held at V<sub>IH</sub> for the device code. The code is read on the eight data pins, O<sub>0</sub>–O<sub>7</sub>. Proper code access is only guaranteed at 25°C  $\pm$  5°C.

### ERASURE CHARACTERISTICS

The erasure characteristics of the device are such that erasure begins to occur when exposed to light with wavelengths shorter than approximately 4000 Angstroms (Å). It should be noted that sunlight and certain types of fluorescent lamps have wavelengths in the 3000Å–4000Å range. The recommended erasure procedure for the EPROM is exposure to short wave ultraviolet light which has a wave-

length of 2537Å. The integrated dose (i.e., UV intensity  $\times$  exposure time) for erasure should be minimum of 15W-sec/cm<sup>2</sup>.

The EPROM should be placed within 1 inch of the lamp tubes during erasure. Some lamps have a filter on their tubes which should be removed before erasure. Table III shows the minimum EPROM erasure time for various light intensities.

An erasure system should be calibrated periodically. The distance from lamp to device should be maintained at one inch. The erasure time increase as the square of the distance from the lamp (if distance is doubled the erasure time increases by factor of 4). Lamps lose intensity as they age. When a lamp is changed, the distance has changed, or the lamp has aged, the system should be checked to make certain full erasure is occurring. Incomplete erasure will cause symptoms that can be misleading. Programmers, components, and even system designs have been erroneously suspected when incomplete erasure was the problem.

### SYSTEM CONSIDERATION

The power switching characteristics of EPROMs require careful decoupling of the devices. The supply current, I<sub>CC</sub>, has three segments that are of interest to the system designer: the standby current level, the active current level, and the transient current peaks that are produced by voltage transitions on input pins. The magnitude of these transient current peaks is dependent of the output capacitance loading of the device. The associated V<sub>CC</sub> transient voltage peaks can be suppressed by properly selected decoupling capacitors. It is recommended that at least a 0.1  $\mu$ F ceramic capacitor be used on every device between V<sub>CC</sub> and GND. This should be a high frequency capacitor of low inherent inductance. In addition, at least a 4.7  $\mu$ F bulk electrolytic capacitor should be used between V<sub>CC</sub> and GND for each eight devices. The bulk capacitor should be located near where the power supply is connected to the array. The purpose of the bulk capacitor is to overcome the voltage drop caused by the inductive effects of the PC board traces.

## Mode Selection

The modes of operation of the NM27P512 are listed in Table I. A single 5V power supply is required in the read mode. All inputs are TTL levels excepts for  $V_{PP}$  and A9 for device signature.

**TABLE I. Mode Selection**

<b>Mode</b>	<b>Pins</b>	<b><math>\overline{CE}/PGM</math></b>	<b><math>\overline{OE}/V_{PP}</math></b>	<b><math>V_{CC}</math></b>	<b>Outputs</b>
