OPERATIONAL EXPLANATION

Typical Application Circuit

Timing Chart

The above uses a timing chart to explain the operation of the circuit indicated in the operation explanation circuit schematic.

(1) In the initial state, an input voltage (VIN) higher than the release voltage (VDR) is applied, and VIN gradually drops.

When a voltage higher than the detect voltage (V_{DFL}) is applied to the input voltage (V_{IN}), the output voltage (V_{OUT}) is equal to the input voltage (V_{IN}).

*On the N-ch open drain output product, the VOUT pin is in a high impedance state, and when the output is pulled up, the output voltage (V_{OUT}) is equal to the pull-up voltage.

(2) When the input voltage (V_{IN}) drops below the detect voltage (V_{DFL}), the output voltage (V_{OUT}) is equal to the ground voltage (V_{SS}). (Detection state)

*This also applies to the N-ch open drain output product.

(3) If the input voltage (V_{IN}) drops below the minimum operating voltage (0.7V), the output becomes unstable.

*If the output pin on the N-ch open drain output product is pulled up, the pull-up voltage may be output as the output voltage (V_{OUT}). (4) The output voltage (V_{OUT}) remains at the ground voltage as the input voltage (V_{IN}) rises past the minimum operating voltage (0.7V)

- and reaches the release voltage (V_{DR}).
- (5) If the input voltage (V_{IN}) rises higher than the release voltage (V_{DR}), the output voltage (V_{OUT}) is equal to the input voltage (V_{IN}).
 *On the N-ch open drain output product, the VOUT pin is in a high impedance state, and if the output is pulled up, the pull-up voltage is output as the output voltage (V_{OUT}) as in (1).
- (6) The difference between the release voltage (V_{DR}) and the detect voltage (V_{DFL}) is the hysteresis width (V_{HYS}).

Note: For simplicity, the above explanation omits the circuit operation time.

NOTE ON USE

- 1. Please use this IC within the stated maximum ratings. For temporary, transitional voltage drop or voltage rising phenomenon, the IC is liable to malfunction should the ratings be exceeded.
- 2. Note that there is a possibility of malfunctioning if the input voltage changes sharply or undergoes repeated, cyclical changes.
- 3. If the resistance R_{IN} is connected between the VIN pin and the power supply V_{DD}, the voltage drop due to the flow through current in the internal circuit and R_{IN} may cause oscillation when release takes place. When using the CMOS output product, oscillation due to R_{IN} and the flow through current may occur without relation to release and detection, and thus R_{IN} should not be connected.
- 4. Please use N-ch open drains configuration, when a resistor R_{IN} is connected between the VIN pin and the power supply V_{DD} . In such cases, please ensure that R_{IN} is less than $33k\Omega$.

[Figure 1: Circuit connected with the input resistor fro N-ch open drain]

5. When N-ch open drain output is used, the V_{OUT} voltage at detection is determined by the pull-up resistance connected to the output pin. Select the resistance based on the following considerations:

At detection: $V_{OUT} = (Vpull-Up)/(1+Rpull/R_{ON})$

Vpull-Up: Voltage after pull-up

R_{ON}(*1): ON resistance of N-ch driver (calculated from V_{OUT}/I_{OUT1} based on electrical characteristics) (*3)

Example:

When V_{IN} = 2.0V (*2), R_{ON} = 0.5/4.5 x 10-3 111 (MAX.). If it is desired to make the V_{OUT} voltage at detection 0.1V or less when Vpull-Up is 3.0 V,

Rpull = (Vpull-Up /V_{OUT-1}) × R_{ON} =(3/0.1-1) × 111 3.2k

Therefore, to make the output voltage at detection 0.1 V or less under the above conditions, the pull-up resistance must be $3.2k\Omega$ or higher.

- (*1) Note that R_{ON} becomes larger as V_{IN} becomes smaller.
- (*2) For V_{IN} in the calculation, use the lowest value of the input voltage range you will use.
- (*3) I_{OUT1} in the electrical characteristics is at Ta = 25 . I_{OUT1} varies depending on the ambient temperature.

To select a pull-up resistance taking ambient temperature into account, consult us.

At release: $V_{OUT} = (Vpull-Up)/(1+Rpull/R_{OFF})$

Vpull-Up: Voltage after pull-up

R_{OFF}: 40M (MIN.) resistance when N-ch driver is OFF (calculated from V_{OUT}/I_{LEAK} based on electrical characteristics) Example:

Making V_{OUT} 5.99 V or higher when Vpull-Up is 6.0 V:

Rpull = $(Vpull-Up/V_{OUT-1}) \times R_{OFF} = (6/5.99-1) \times 40 \times 106$ 66 k

Therefore, to make the output voltage at release 5.99 V or higher under the above conditions, the pull-up resistance must be $66k\Omega$ or less.
