

FEATURES

6th-order performance, low-pass video filter

1 dB flatness out to 8 MHz

50 dB rejection at 27 MHz

Ultralow power-down current: 0.1 μ A typ

Low quiescent current: 1.85 mA typ

Excellent video specification

Differential gain: 0.25%

Differential phase: 0.10°

SAG correction

Allows use of small capacitors in ac-coupled outputs

Low supply voltage: 2.5 V to 6 V

Rail-to-rail output

High input-to-output isolation in disabled state

92 dB @ 1 MHz

Low input bias current: 0.5 μ A

Small packaging: SC70

Wide operating temperature range: -40°C to +125°C

APPLICATIONS

Portable media players

Portable gaming consoles

Cell phones

Digital still cameras

Portable DVD players

Portable video cameras

PIN CONFIGURATION

Figure 1.

Figure 2. Frequency Response Flatness at Various Power Supplies

GENERAL DESCRIPTION

The ADA4430-1 is a fully integrated video reconstruction filter that combines excellent video specifications with low power consumption and an ultralow power disable, making it ideal for portable video filtering applications. With 1 dB frequency flatness out to 8 MHz and 50 dB rejection at 27 MHz, the ADA4430-1 is ideal in SD video applications, including NTSC and PAL.

The ADA4430-1 operates on single supplies as low as 2.5 V and as high as 6 V while providing the dynamic range required by the most demanding video systems.

The ADA4430-1 also provides an on-chip dc offset to avoid clipping of the sync tips at the filter output, as well as SAG correction that permits smaller capacitor values to be used in applications with ac-coupled outputs.

The ADA4430-1 is available in a 6-lead SC70 package and is rated to work in the extended automotive temperature range of -40°C to +125°C.

ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameter	Rating
Supply Voltage	6 V
Power Dissipation	See Figure 3
Storage Temperature Range	–65°C to +125°C
Operating Temperature Range	–40°C to +125°C
Lead Temperature (Soldering 10 sec)	300°C
Junction Temperature	150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL RESISTANCE

θ_{JA} is specified for the worst-case conditions, that is, θ_{JA} is specified for a device soldered in the circuit board.

Table 4. Thermal Resistance

Package Type	θ_{JA}	Unit
6-Lead SC70	430	°C/W

Maximum Power Dissipation

The maximum safe power dissipation in the ADA4430-1 package is limited by the associated rise in junction temperature (T_J) on the die. At approximately 150°C, which is the glass transition temperature, the plastic changes its properties. Even temporarily exceeding this temperature limit can change the stresses that the package exerts on the die, permanently shifting the parametric performance of the ADA4430-1. Exceeding a junction temperature of 150°C for an extended period can result in changes in the silicon devices potentially causing failure.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

The power dissipated in the package (P_D) is the sum of the quiescent power dissipation and the power dissipated in the package due to the load drive. The quiescent power is the voltage between the supply pins (V_S) times the quiescent current (I_S). The power dissipated due to the load drive depends upon the particular application. The power due to load drive is calculated by multiplying the load current by the associated voltage drop across the device. RMS voltages and currents must be used in these calculations.

Airflow increases heat dissipation, effectively reducing θ_{JA} . In addition, more metal directly in contact with the package leads from metal traces, through-holes, ground, and power planes reduces the θ_{JA} .

Figure 3 shows the maximum safe power dissipation in the package vs. the ambient temperature for the 6-lead SC70 (430°C/W) on a JEDEC standard 4-layer board.

Figure 3. Maximum Power Dissipation vs. Temperature for a 4-Layer Board

THEORY OF OPERATION

OVERVIEW

The ADA4430-1 is designed for exceptional performance as both a filter and a low power driver for portable video applications. This performance is achieved by providing high order filtering without trading off power consumption or device size. While consuming only 1.85 mA quiescent supply current, the ADA4430-1 provides video output on a single-supply as low as 2.5 V. Such low power consumption and low supply operation would normally indicate a single op amp with a 2- or 3-pole roll-off; however, the ADA4430-1 achieves a sixth-order roll-off in addition to a 10 M Ω input impedance for easy clamping and lower DAC output power requirements. When not in use, the ADA4430-1 can be shutdown to draw less than 1 μ A of supply current using the power-down pin, ($\overline{\text{PD}}$). Additionally, the ADA4430-1 is unique in that it is a high order filter that fits into an SC70 package.

The ADA4430-1 provides a minimum 1 dB bandwidth of 5.5 MHz and a minimum stop-band rejection of 42 dB at 27 MHz. Phase response is not sacrificed in spite of the exceptional filtering performance of the ADA4430-1, as exhibited by its group delay, which varies by only 7 ns from 100 kHz to 5 MHz.

The ADA4430-1 is intended for use in applications that have both ac- and dc-coupled inputs and outputs. The rail-to-rail buffer on the ADA4430-1 output is able to drive 2 V p-p video signals into two doubly-terminated video loads (150 Ω each) on a single 2.5 V supply. The ADA4430-1 has a gain of 2 when the SAG correction pin is tied directly to the output, which makes up for the 6 dB termination loss. When the SAG feature is used (see Figure 29), the ADA4430-1 has a low frequency gain of 2.5 (\approx 8 dB) and a high frequency gain of 2. Signal offsets and supply levels must be considered when using the SAG correction feature to ensure that there are no headroom issues.

The input range of the ADA4430-1 includes ground, while the output range is limited by the saturation of the output devices. Saturation occurs several tens of mV from the positive and negative supply rails. For accurate reproduction of ground-referenced input signals, an internal offset is used to shift the output up by 95 mV.

The high input impedance and low input capacitance of the ADA4430-1 offer advantages in a number of low power applications. In reconstruction filter applications, the DAC can be placed in its lowest power mode, allowing the use of a large-valued load resistor. Using a large-valued load resistor does not interfere with the frequency response of the ADA4430-1.

The internal buffer at the ADA4430-1 input isolates the source resistance feeding the ADA4430-1 from the internal filter networks. High input impedance is also advantageous when using video clamping circuits.

The output buffer feedback network used to create a gain of 2 is connected internally to the GND pin and has a nominal impedance of 5.2 k Ω . The current required to drive this feedback network causes the overall supply current to vary based on the output level. The feedback impedance was chosen specifically to minimize excess current consumption while maintaining optimal frequency behavior.

POWER SAVINGS USING THE ADA4430-1

Using a series source termination and a shunt load termination on a low supply voltage with the ADA4430-1 realizes significant power savings compared with driving a video cable directly from a DAC output. Figure 27 shows a video DAC driving a cable directly. Properly terminating the line results in the DAC driving two 75 Ω loads and requires in excess of 30 mA to reach a full-scale level of 1.3 V. Figure 28 shows the same video load being driven using the ADA4430-1 and a series-shunt termination. This requires two times the output voltage to drive the equivalent of 150 Ω but only requires a little more than 15 mA to reach a full-scale output. When running on the same supply voltage as the DAC, this results in nearly a factor of two reduction in power compared with the circuit in Figure 27. The high level of filtering provided by the ADA4430-1 lowers the requirements on the DAC oversampling ratio, realizing further power savings. On any given DAC, 8 \times and 16 \times oversampling ratios can require twice the power consumption of a 4 \times oversampling ratio.

APPLICATIONS

EXAMPLES ILLUSTRATING OUTPUT COUPLING

The ADA4430-1 is ideally suited for use as a reconstruction filter that follows a video DAC or encoder. The application circuits in Figure 29, Figure 30, and Figure 31 illustrate a number of ways the ADA4430-1 can be used with a single-supply current-output DAC on its input and its output ac- and dc-coupled.

SAG correction allows the use of two small, lower cost capacitors in place of one large capacitor in applications with ac-coupled outputs. Circuits with ac-coupled outputs consume less power than those with dc-coupled outputs.

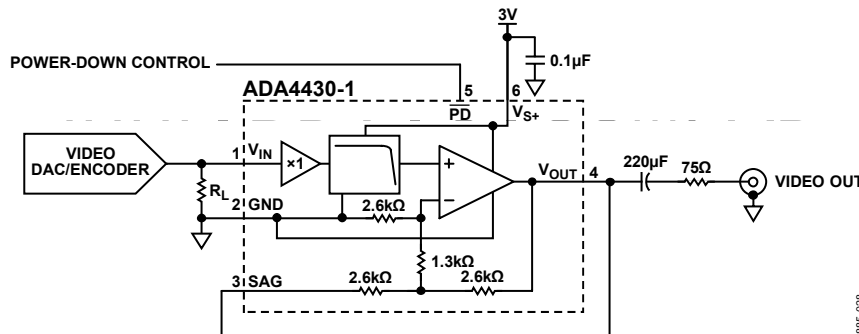

Figure 30. Traditional AC-Coupled Output with 220 μF Coupling Capacitor

05885-028

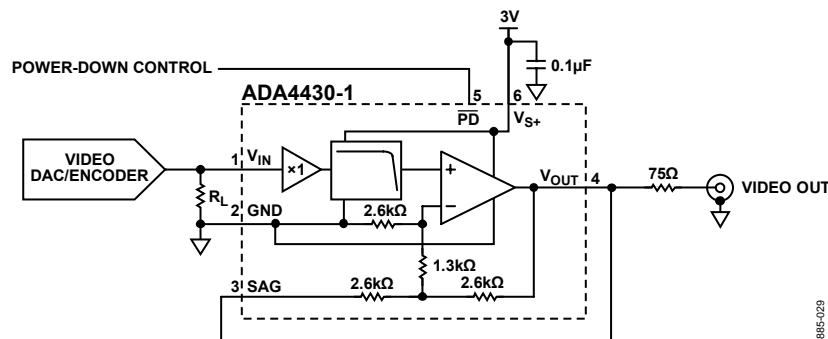

Figure 31. DC-Coupled Output

05885-029

USABLE INPUT VOLTAGE RANGE

The output voltage range of the ADA4430-1 limits its usable input voltage range. The lower end of the input range is typically 0 V. The upper end of the usable input voltage range is calculated as

$$V_{IN(max)} = (V_{OM} - V_{OO})/2$$

where:

$V_{IN(max)}$ is the upper end of the usable input voltage range.

V_{OM} is the maximum output swing.

V_{OO} is the output-referred offset voltage.

SAG CORRECTION FREQUENCY RESPONSE

When using the SAG corrected circuit, the gain from the input to the immediate output of the ADA4430-1 is $\times 2.5$ (≈ 8 dB) at extremely low frequencies where the outer feedback loop formed by the 22 μ F capacitor effectively opens (see Figure 29) and exhibits a second-order peak of approximately 11 dB in the neighborhood of 5 Hz. This gain is approximately 7.5 dB at 30 Hz. The extra gain must be accounted for when considering low frequency input and output signal swings to keep them within their specified limits. The gain from the ADA4430-1 input to the load side of the 47 μ F capacitor does not exhibit this behavior, rather it appears more like a single-pole high-pass response. Figure 32 illustrates the SAG frequency response immediately at the ADA4430-1 output and at the load side of the 47 μ F capacitor.

Figure 32. SAG Corrected Frequency Response at ADA4430-1 Output and at the Load Side of the 47 μ F Capacitor

ADA4430-1

RECONSTRUCTION FILTER APPLICATIONS

Figure 33 illustrates how to use the ADA4430-1 as a dc-coupled reconstruction filter with a pass band gain of 2 following the low power [ADV7190/ADV7191](#) video encoder. One [ADV7190/ADV7191](#) output DAC is shown for illustrative purposes, and the remaining portions of the [ADV7190/ADV7191](#) are omitted. The [ADV7190/ADV7191](#) is operated in 4× oversampling mode.

The 2.4 kΩ resistor, R_{SET} , shown in Figure 33 sets the DAC output current to its minimum full-scale value of 2.16 mA, and the 600 Ω load resistor produces a full-scale voltage of 1.296 V at the ADA4430-1 input.

Figure 34 illustrates another reconstruction filter application, following the [ADV7174](#) video encoder. As in Figure 33, one [ADV7174](#) output DAC is shown for illustrative purposes, and the remaining portions of the [ADV7174](#) are omitted.

The 1041 Ω resistor, R_{SET} , shown in Figure 34, sets the DAC output current to its minimum full-scale value of 5 mA, and the 262.5 Ω load resistor produces a full-scale voltage of 1.313 V at the ADA4430-1 input.

The [ADV7174](#) can produce a maximum full-scale DAC output current of approximately 35 mA and is therefore capable of driving the video cable directly; however, as is shown in Figure 34, the ADA4430-1 offers a lower, power cable-driving option.

Figure 34 reveals the details of how the ADA4430-1 saves power when driving video cables with terminations at both ends. A full-scale level at the DAC output produces 2.626 V at the ADA4430-1 output, which in turn delivers 17.5 mA into the cable. In the case shown in Figure 27, the output voltage is 1.313 V, but the current driven into the cable is 35 mA – twice that required when the ADA4430-1 is used. Therefore, the ADA4430-1 allows the video encoder to be operated at its minimum full-scale output current, and it efficiently handles the cable-driving burden.

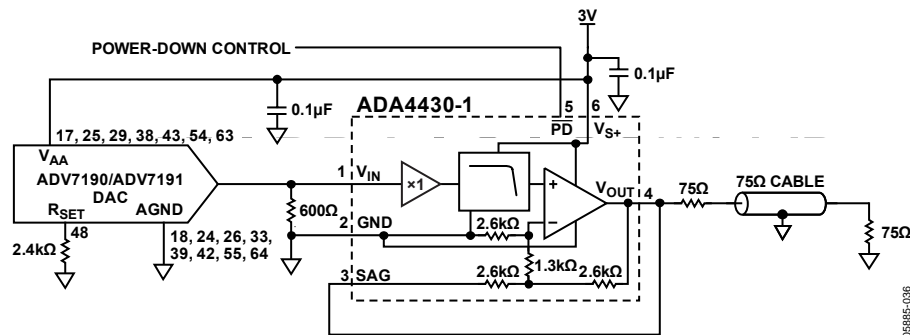

Figure 33. Using the ADA4430-1 with the ADV7190/ADV7191 Video Encoder

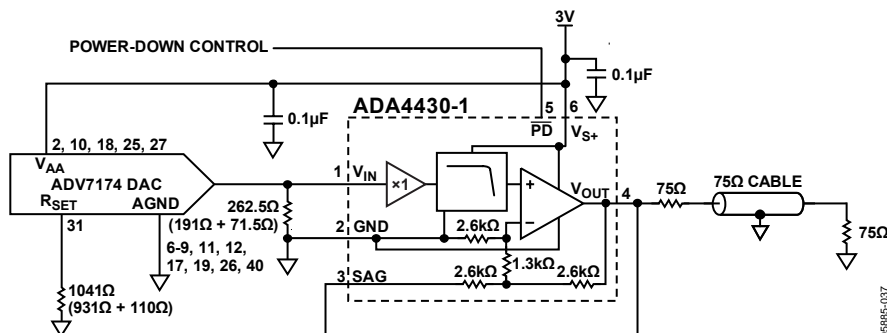

Figure 34. Using the ADA4430-1 with the ADV7174 Video Encoder

PRINTED CIRCUIT BOARD LAYOUT

As with all high speed applications, attention to printed circuit board layout is of paramount importance. Standard high speed layout practices should be adhered to when designing with the ADA4430-1. A solid ground plane is recommended, and a 0.1 μ F surface-mount, ceramic power supply, decoupling capacitor should be placed as close as possible to the supply pin.

The GND pin should be connected to the ground plane with a trace that is as short as possible. Controlled impedance traces of the shortest length possible should be used to connect to the signal I/O pins and should not pass over any voids in the ground plane. A 75 Ω impedance level is typically used in video applications. All signal outputs of the ADA4430-1 should include series termination resistors when driving transmission lines.

When the ADA4430-1 receives its inputs from a device with current outputs, the required load resistor value for the output current is most often different from the characteristic impedance of the signal traces. In this case, if the interconnections are sufficiently short (less than 2 inches), the trace does not have to be terminated in its characteristic impedance.
