

### FEATURES

#### High speed

800 MHz, -3 dB bandwidth

790 V/ $\mu$ s slew rate

8 ns settling time to 0.5%

#### Wide supply range: 5 V to 12 V

#### Low power: 6 mA

0.1 dB flatness: 125 MHz

Differential gain: 0.02%

Differential phase: 0.02°

Low voltage offset: 3.5 mV (typ)

High output current: 25 mA

Power down

### APPLICATIONS

Consumer video

Professional video

Broadband video

ADC buffers

Active filters

### GENERAL DESCRIPTION

The ADA4860-1 is a low cost, high speed, current feedback op amp that provides excellent overall performance. The 800 MHz, -3 dB bandwidth, and 790 V/ $\mu$ s slew rate make this amplifier well suited for many high speed applications. With its combination of low price, excellent differential gain (0.02%), differential phase (0.02°), and 0.1 dB flatness out to 125 MHz, this amplifier is ideal for both consumer and professional video applications.

The ADA4860-1 is designed to operate on supply voltages as low as +5 V and up to  $\pm 5$  V using only 6 mA of supply current. To further reduce power consumption, the amplifier is equipped with a power-down feature that lowers the supply current to 0.25 mA.

The ADA4860-1 is available in a 6-lead SOT-23 package and is designed to work over the extended temperature range of -40°C to +105°C.

## ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameter	Rating
Supply Voltage	12.6 V
Power Dissipation	See Figure 3
Common-Mode Input Voltage	–V <sub>S</sub> + 1 V to +V <sub>S</sub> – 1 V
Differential Input Voltage	±V <sub>S</sub>
Storage Temperature Range	–65°C to +125°C
Operating Temperature Range	–40°C to +105°C
Lead Temperature	JEDEC J-STD-20
Junction Temperature	150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### THERMAL RESISTANCE

$\theta_{JA}$  is specified for the worst-case conditions, that is,  $\theta_{JA}$  is specified for device soldered in circuit board for surface-mount packages.

Table 4. Thermal Resistance

Package Type	$\theta_{JA}$	Unit
6-lead SOT-23	170	°C/W

### Maximum Power Dissipation

The maximum safe power dissipation for the ADA4860-1 is limited by the associated rise in junction temperature ( $T_J$ ) on the die. At approximately 150°C, which is the glass transition temperature, the plastic changes its properties. Even temporarily exceeding this temperature limit can change the stresses that the package exerts on the die, permanently shifting the parametric performance of the amplifiers. Exceeding a junction temperature of 150°C for an extended period can result in changes in silicon devices, potentially causing degradation or loss of functionality.

The power dissipated in the package ( $P_D$ ) for a sine wave and a resistor load is the total power consumed from the supply minus the load power.

$$P_D = \text{Total Power Consumed} - \text{Load Power}$$

$$P_D = \left( V_{\text{SUPPLY VOLTAGE}} \times I_{\text{SUPPLY CURRENT}} \right) - \frac{V_{\text{OUT}}^2}{R_L}$$

RMS output voltages should be considered.

Airflow across the ADA4860-1 helps remove heat from the package, effectively reducing  $\theta_{JA}$ . In addition, more metal directly in contact with the package leads and through holes under the device reduces  $\theta_{JA}$ .

Figure 3 shows the maximum safe power dissipation in the package vs. the ambient temperature for the 6-lead SOT-23 (170°C/W) on a JEDEC standard 4-layer board.  $\theta_{JA}$  values are approximations.

Figure 3. Maximum Power Dissipation vs. Temperature for a 4-Layer Board

### ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## TYPICAL PERFORMANCE CHARACTERISTICS

## APPLICATION INFORMATION

### POWER SUPPLY BYPASSING

Attention must be paid to bypassing the power supply pins of the ADA4860-1. High quality capacitors with low equivalent series resistance (ESR), such as multilayer ceramic capacitors (MLCCs), should be used to minimize supply voltage ripple and power dissipation. Generally, a 10  $\mu\text{F}$  tantalum capacitor located in close proximity to the ADA4860-1 is required to provide good decoupling for lower frequency signals. In addition, a 0.1  $\mu\text{F}$  decoupling multilayer ceramic chip capacitor (MLCC) should be located as close to each of the power supply pins as is physically possible, no more than  $\frac{1}{8}$  inch away. The ground returns should terminate immediately into the ground plane. Locating the bypass capacitor return close to the load return minimizes ground loops and improves performance.

### FEEDBACK RESISTOR SELECTION

The feedback resistor has a direct impact on the closed-loop bandwidth and stability of the current feedback op amp circuit. Reducing the resistance below the recommended value can make the amplifier response peak and even become unstable. Increasing the size of the feedback resistor reduces the closed-loop bandwidth. Table 5 provides a convenient reference for quickly determining the feedback and gain set resistor values and bandwidth for common gain configurations.

**Table 5. Recommended Values and Frequency Performance<sup>1</sup>**

Gain	$R_F$ ( $\Omega$ )	$R_G$ ( $\Omega$ )	-3 dB SS BW (MHz)	-3 dB LS BW (MHz)	Large Signal 0.1 dB Flatness
+1	550	N/A	800	165	40
-1	499	499	400	400	80
+2	499	499	520	230	125
+5	348	86.6	335	265	100
+10	348	38.3	165	195	28

<sup>1</sup> Conditions:  $V_S = \pm 5\text{ V}$ ,  $T_A = 25^\circ\text{C}$ ,  $R_L = 150\ \Omega$ .

Figure 51 and Figure 52 show the typical noninverting and inverting configurations and the recommended bypass capacitor values.

Figure 51. Noninverting Gain

Figure 52. Inverting Gain

## DRIVING CAPACITIVE LOADS

If driving loads with a capacitive component is desired, the best frequency response is obtained by the addition of a small series resistance, as shown in Figure 53. Figure 54 shows the optimum value for  $R_{\text{SERIES}}$  vs. capacitive load. The test was performed with a 50 MHz, 50% duty cycle pulse, with an amplitude of 200 mV p-p. The criteria for  $R_{\text{SERIES}}$  selection was based on maintaining approximately 1 dB of peaking in small signal frequency response. It is worth noting that the frequency response of the circuit can be dominated by the passive roll-off of  $R_{\text{SERIES}}$  and  $C_L$ .

Figure 53. Driving Capacitive Loads

Figure 54. Recommended  $R_{\text{SERIES}}$  vs. Capacitive Load

## POWER DOWN PIN

The ADA4860-1 is equipped with a power-down function. The POWER DOWN pin allows the user to reduce the quiescent supply current when the amplifier is not being used. The power-down threshold levels are derived from the voltage applied to the  $-V_S$  pin. When used in single-supply applications, this is especially useful with conventional logic levels. The amplifier is powered down when the voltage applied to the POWER DOWN pin is greater than  $(-V_S + 0.5 \text{ V})$ . The amplifier is enabled whenever the POWER DOWN pin is left open, or the voltage on the POWER DOWN pin is less than  $(-V_S + 0.5 \text{ V})$ . If the POWER DOWN pin is not used, it should be connected to the negative supply.

## VIDEO AMPLIFIER

With low differential gain and phase errors and wide 0.1 dB flatness, the ADA4860-1 is an ideal solution for consumer and professional video applications. Figure 55 shows a typical video driver set for a noninverting gain of +2, where  $R_F = R_G = 499 \Omega$ . The video amplifier input is terminated to a shunt 75  $\Omega$  resistor. At the output, the amplifier has a series 75  $\Omega$  resistor for impedance matching to the video load.

Figure 55. Video Driver Schematic

## SINGLE-SUPPLY OPERATION

Single-supply operation can present certain challenges for the designer. For a detailed explanation on op amp single-supply operation, see Application Note [AN-581](#).

## OPTIMIZING FLATNESS AND BANDWIDTH

When using the ADA4860-1, a variety of circuit conditions and parasitics can affect peaking, gain flatness, and  $-3$  dB bandwidth. This section discusses how the ADA4860-1 small signal responses can be dramatically altered with basic circuit changes and added stray capacitances, see the Layout and Circuit Board Parasitics section for more information.

Particularly with low closed-loop gains, the feedback resistor ( $R_F$ ) effects peaking and gain flatness. However, with gain = +1,  $-3$  dB bandwidth varies slightly, while gain = +2 has a much larger variation. For gain = +1, Figure 56 shows the effect that various feedback resistors have on frequency response. In Figure 56, peaking is wide ranging yet  $-3$  dB bandwidths vary by only 6%. In this case, the user must pick what is desired: more peaking or flatter bandwidth. Figure 57 shows gain = +2 bandwidth and peaking variations vs.  $R_F$  and  $R_L$ . Bandwidth delta vs.  $R_L$  increase was approximately 17%. As  $R_F$  is reduced from 560  $\Omega$  to 301  $\Omega$ , the  $-3$  dB bandwidth changes 49%, with excessive compromises in peaking, see Figure 57. For more gain = +2 bandwidth variations vs.  $R_F$ , see Figure 10 and Figure 13.

Figure 56. Small Signal Frequency Response vs.  $R_F$

Figure 57. Small Signal Frequency Response vs.  $R_F$  vs.  $R_L$

The impact of resistor case sizes was observed using the circuit drawn in Figure 58. The types and sizes chosen were 0402 case sized thin film and 1206 thick film. All other measurement conditions were kept constant except for the case size and resistor composition.

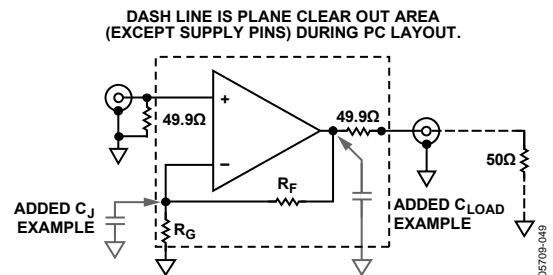

Figure 58. Noninverting Gain Setup for Illustration of Parasitic Effects, 50  $\Omega$  System,  $R_L = 100 \Omega$

In Figure 59, a slight  $-3$  dB bandwidth delta of approximately +10% can be seen going from a small-to-large case size. The increase in bandwidth with the larger 1206 case size is caused by an increase in parasitic capacitance across the chip resistor.

Figure 59. Small Signal Frequency Response vs. Resistor Size

## LAYOUT AND CIRCUIT BOARD PARASITICS

Careful attention to printed circuit board (PCB) layout prevents associated board parasitics from becoming problematic and affecting gain flatness and  $-3$  dB bandwidth. In the printed circuit environment, parasitics around the summing junction (inverting input) or output pins can alter pulse and frequency response. Parasitic capacitance can be unintentionally created on a PC board via two parallel metal planes with a small vertical separation (in FR4). To avoid parasitic problems near the summing junction, signal line connections between the feedback and gain resistors should be kept as short as possible to minimize the inductance and stray capacitance. For similar reasons, termination and load resistors should be located as close as possible to the respective inputs. Removing the ground plane on all layers from the area near and under the input and output pins reduces stray capacitance.

To illustrate the affects of parasitic capacitance, a small capacitor of  $0.4$  pF from the amplifiers summing junction (inverting input) to ground was intentionally added. This was done on two boards with equal and opposite gains of  $+2$  and  $-2$ . Figure 60 reveals the effects of parasitic capacitance at the summing junction for both noninverting and inverting gain circuits. With gain  $= +2$ , the additional  $0.4$  pF of added capacitance created an extra 43%  $-3$  dB bandwidth extension, plus some extra peaking. For gain  $= -2$ , a 5% increase in  $-3$  dB bandwidth was created with an extra  $0.4$  pF on summing junction.

Figure 60. Small Signal Frequency Response vs. Added Summing Junction Capacitance

In a second test,  $5.6$  pF of capacitance was added directly at the output of the gain  $= +2$  amplifier. Figure 61 shows the results. Extra output capacitive loading on the ADA4860-1 also causes bandwidth extensions, as seen in Figure 61. The effect on the gain  $= +2$  circuit is more pronounced with lighter resistive loading ( $1$  k $\Omega$ ). For pulse response behavior with added output capacitances, see Figure 23, Figure 24, Figure 26, Figure 27, Figure 29, Figure 30, Figure 32, and Figure 33.
