

Multiformat SDTV Video Decoder

ADV7189B

FEATURES

- Multiformat video decoder supports NTSC-(J, M, 4.43), PAL-(B/D/G/H/I/M/N), SECAM
- Integrates three 54 MHz, Noise Shaped Video[®], 12-bit ADCs
- Clocked from a single 28 MHz crystal
- Line-locked clock-compatible (LLC)
- Adaptive-Digital-Line-Length-Tracking (ADLLT[™]), signal processing, and enhanced FIFO management gives mini-TBC functionality
- 5-line adaptive comb filters
- Proprietary architecture for locking to weak, noisy, and unstable video sources such as VCRs and tuners
- Subcarrier frequency lock and status information output
- Integrated AGC with adaptive peak white mode
- Macrovision[®] copy protection detection
- CTI (chroma transient improvement)
- DNR (digital noise reduction)
- Multiple programmable analog input formats
 - CVBS (composite video)
 - S-Video (Y/C)
 - YPrPb component (VESA, MII, SMPTE, and BetaCam)
- 12 analog video input channels
- Automatic NTSC/PAL/SECAM identification
- Digital output formats (8-bit/10-bit/16-bit/20-bit)
 - ITU-R BT.656 YCrCb 4:2:2 output + HS, VS, and FIELD

GENERAL DESCRIPTION

The ADV7189B integrated video decoder automatically detects and converts a standard analog baseband television signal, compatible with worldwide standards NTSC, PAL, and SECAM into 4:2:2 component video data-compatible with 20-, 16-, 10-, and 8-bit CCIR601/CCIR656.

The advanced and highly flexible digital output interface enables performance video decoding and conversion in line-locked, clock-based systems. This makes the device ideally suited for a broad range of applications with diverse analog video characteristics, including tape-based sources, broadcast sources, security/surveillance cameras, and professional systems.

The 12-bit accurate A/D conversion provides professional quality video performance and is unmatched. This allows true 10-bit resolution in the 10-bit output mode.

Rev. B

Information furnished by Analog Devices is believed to be accurate and reliable. However, no responsibility is assumed by Analog Devices for its use, nor for any infringements of patents or other rights of third parties that may result from its use. Specifications subject to change without notice. No license is granted by implication or otherwise under any patent or patent rights of Analog Devices. Trademarks and registered trademarks are the property of their respective owners.

- 0.5 V to 1.6 V analog signal input range
- Differential gain: 0.4% typ
- Differential phase: 0.4° typ
- Programmable video controls
 - Peak white/hue/brightness/saturation/contrast
- Integrated on-chip video timing generator
- Free-run mode (generates stable video output with no I/P)
- VBI decode support for close captioning, WSS, CGMS, EDTV, Gemstar[®] 1x/2x
- Power-down mode
- 2-wire serial MPU interface (I²C[®]-compatible)
- 3.3 V analog, 1.8 V digital core; 3.3 V IO supply
- 2 temperature grades: 0°C to +70°C and -40°C to +85°C
- 80-lead LQFP Pb-free package

APPLICATIONS

- High-end DVD recorders
- Video projectors
- HDD-based PVRs/DVDRs
- LCD TVs
- Set-top boxes
- Professional video products
- AVR receivers

The 12 analog input channels accept standard composite, S-Video, YPrPb video signals in an extensive number of combinations. AGC and clamp restore circuitry allow an input video signal peak-to-peak range of 0.5 V to 1.6 V. Alternatively, these can be bypassed for manual settings.

The fixed 54 MHz clocking of the ADCs and datapath for all modes allows very precise, accurate sampling and digital filtering. The line-locked clock output allows the output data rate, timing signals, and output clock signals to be synchronous, asynchronous, or line locked even with $\pm 5\%$ line length variation. The output control signals allow glueless interface connections in almost any application. The ADV7189B modes are set up over a 2-wire, serial, bidirectional port (I²C-compatible).

The ADV7189B is fabricated in a 3.3 V CMOS process. Its monolithic CMOS construction ensures greater functionality with lower power dissipation. The ADV7189B is packaged in a small, 80-lead LQFP Pb-free package.

INTRODUCTION

The ADV7189B is a high quality, single chip, multiformat video decoder that automatically detects and converts PAL, NTSC, and SECAM standards in the form of composite, S-Video, and component video into a digital ITU-R BT.656 format.

The advanced and highly flexible digital output interface enables performance video decoding and conversion in line-locked, clock-based systems. This makes the device ideally suited for a broad range of applications with diverse analog video characteristics, including tape-based sources, broadcast sources, security/ surveillance cameras, and professional systems.

ANALOG FRONT END

The ADV7189B analog front end comprises three 12-bit noise shaped video ADCs that digitize the analog video signal before applying it to the standard definition processor. The analog front end employs differential channels to each ADC to ensure high performance in mixed-signal applications.

The front end also includes a 12-channel input mux that enables multiple video signals to be applied to the ADV7189B. Current and voltage clamps are positioned in front of each ADC to ensure the video signal remains within the range of the converter. Fine clamping of the video signals is performed downstream by digital fine clamping within the ADV7189B. The ADCs are configured to run in 4× oversampling mode.

STANDARD DEFINITION PROCESSOR

The ADV7189B is capable of decoding a large selection of base-band video signals in composite, S-Video, and component formats. The video standards supported by the ADV7189B include PAL B/D/I/G/H, PAL60, PAL M, PAL N, PAL Nc, NTSC M/J, NTSC 4.43, and SECAM B/D/G/K/L. The ADV7189B can automatically detect the video standard and process it accordingly. The ADV7189B has a 5-line, super-adaptive, 2D comb filter that gives superior chrominance and luminance separation when decoding a composite video signal. This highly adaptive filter automatically adjusts its processing mode according to video standard and signal quality with no user intervention required. Video user controls such as brightness, contrast, saturation, and hue are also available within the ADV7189B.

The ADV7189B implements a patented adaptive-digital-line-length-tracking (ADLLT) algorithm to track varying video line lengths from sources such as a VCR. ADLLT enables the ADV7189B to track and decode poor quality video sources such as VCRs, noisy sources from tuner outputs, VCD players, and camcorders. The ADV7189B contains a chroma transient improvement (CTI) processor that sharpens the edge rate of chroma transitions, resulting in sharper vertical transitions.

The ADV7189B can process a variety of VBI data services, such as closed captioning (CC), wide screen signaling (WSS), copy generation management system (CGMS), EDTV, Gemstar 1×/2×, and extended data service (XDS). The ADV7189B is fully Macrovision certified; detection circuitry enables Type I, Type II, and Type III protection levels to be identified and reported to the user. The decoder is also fully robust to all Macrovision signal inputs.

ABSOLUTE MAXIMUM RATINGS

Table 6.

Parameter	Rating
A_{VDD} to GND	4 V
A_{VDD} to AGND	4 V
D_{VDD} to DGND	2.2 V
P_{VDD} to AGND	2.2 V
D_{VDDIO} to DGND	4 V
D_{VDDIO} to A_{VDD}	-0.3 V to +0.3 V
P_{VDD} to D_{VDD}	-0.3 V to +0.3 V
$D_{VDDIO} - P_{VDD}$	-0.3 V to +2 V
$D_{VDDIO} - D_{VDD}$	-0.3 V to +2 V
$A_{VDD} - P_{VDD}$	-0.3 V to +2 V
$A_{VDD} - D_{VDD}$	-0.3 V to +2 V
Digital Inputs Voltage to DGND	-0.3 V to $D_{VDDIO} + 0.3$ V
Digital Output Voltage to DGND	-0.3 V to $D_{VDDIO} + 0.3$ V
Analog Inputs to AGND	AGND - 0.3 V to $A_{VDD} + 0.3$ V
Maximum Junction Temperature (T_J Max)	150°C
Storage Temperature Range	-65°C to +150°C
Infrared Reflow Soldering (20 sec)	260°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 5. 80-Lead LQFP Pin Configuration

Table 7. Pin Function Descriptions

Pin No.	Mnemonic	Type	Function
3, 9, 14, 31, 71	DGND	G	Digital Ground.
39, 40, 47, 53, 56	AGND	G	Analog Ground.
4, 15	DVDDIO	P	Digital I/O Supply Voltage (3.3 V).
10, 30, 72	DVDD	P	Digital Core Supply Voltage (1.8 V).
50	AVDD	P	Analog Supply Voltage (3.3 V).
38	PVDD	P	PLL Supply Voltage (1.8 V).
42, 44, 46, 58, 60, 62, 41, 43, 45, 57, 59, 61	AIN1toAIN12	I	Analog Video Input Channels.
11	$\overline{\text{INTRQ}}$	O	Interrupt Request Output. Interrupt occurs when certain signals are detected on the input video. See the interrupt register map in Table 86.
13, 16, 25, 63, 65, 69, 70, 77, 78	NC		No Connect Pins.
35 to 32, 24 to 17, 8 to 5, 76 to 73	P0–P19	O	Video Pixel Output Port.
2	HS	O	Horizontal Synchronization Output Signal.
1	VS	O	Vertical Synchronization Output Signal.
80	FIELD	O	Field Synchronization Output Signal.
67	SDA	I/O	I ² C Port Serial Data Input/Output Pin.
68	SCLK	I	I ² C Port Serial Clock Input (Max Clock Rate of 400 kHz).
66	ALSB	I	This pin selects the I ² C address for the ADV7189B. ALSB set to a Logic 0 sets the address for a write as 0x40; for ALSB set to a logic high, the address selected is 0x42.
64	$\overline{\text{RESET}}$	I	System Reset Input, Active Low. A minimum low reset pulse width of 5 ms is required to reset the ADV7189B circuitry.
27	LLC1	O	This is a line-locked output clock for the pixel data output by the ADV7189B. Nominally 27 MHz, but varies up or down according to video line length.
26	LLC2	O	This is a divide-by-2 version of the LLC1 output clock for the pixel data output by the ADV7189B. Nominally 13.5 MHz, but varies up or down according to video line length.
29	XTAL	I	This is the input pin for the 28.6363 MHz crystal, or can be overdriven by an external 3.3 V, 27 MHz clock oscillator source. In crystal mode, the crystal must be a fundamental crystal.
28	XTAL1	O	This pin should be connected to the 28.6363 MHz crystal or left as a no connect if an external 3.3 V, 27 MHz clock oscillator source is used to clock the ADV7189B. In crystal mode, the crystal must be a fundamental crystal.
36	$\overline{\text{PWRDN}}$	I	A logic low on this pin places the ADV7189B in a power-down mode. Refer to Power Management Register in the I2C Register Maps section for more options on power-down modes for the ADV7189B.
79	$\overline{\text{OE}}$	I	When set to a logic low, $\overline{\text{OE}}$ enables the pixel output bus, P19 to P0 of the ADV7189B. A logic high on the $\overline{\text{OE}}$ pin places Pins P19 to P0, HS, VS, SFL into a high impedance state.
37	ELPF	I	The recommended external loop filter must be connected to this ELPF pin, as shown in Figure 46.
12	SFL	O	Subcarrier Frequency Lock. This pin contains a serial output stream that can be used to lock the subcarrier frequency when this decoder is connected to any Analog Devices, Inc. digital video encoder.
51	REFOUT	O	Internal Voltage Reference Output. Refer to Figure 46 for a recommended capacitor network for this pin.
52	CML	O	The CML pin is a common-mode level for the internal ADCs. Refer to Figure 46 for a recommended capacitor network for this pin.
48, 49	CAPY1, CAPY2	I	ADC's Capacitor Network. Refer to Figure 46 for a recommended capacitor network for this pin.
54, 55	CAPC1, CAPC2	I	ADC's Capacitor Network. Refer to Figure 46 for a recommended capacitor network for this pin.

ANALOG FRONT END

ANALOG INPUT MUXING

Figure 6. Internal Pin Connections

The ADV7189B has an integrated analog muxing section that allows more than one source of video signal to be connected to the decoder. Figure 6 outlines the overall structure of the input muxing provided in the ADV7189B.

As can be seen in Figure 6, there are two different ways in which the analog input muxes can be controlled:

- Control via functional registers (INSEL). Using INSEL[3:0] simplifies the setup of the muxes, and minimizes crosstalk between channels by pre-assigning the input channels. This is referred to as ADI recommended input muxing.
- Control via an I²C manual override (ADC_sw_man_en, ADC0_sw, ADC1_sw, ADC2_sw). This is provided for applications with special requirements, for example, number/combinations of signals that would not be served by the pre-assigned input connections. This is referred to as manual input muxing.

Refer to Figure 7 for an overview of the two methods of controlling the ADV7189B's input muxing.

ADI Recommended Input Muxing

A maximum of 12 CVBS inputs can be connected and decoded by the ADV7189B. As seen in Figure 5, this means the sources have to be connected to adjacent pins on the IC. This calls for a careful design of the PCB layout, for example, ground shielding between all signals routed through tracks that are physically close together.

INSEL[3:0] Input Selection, Address 0x00[3:0]

The INSEL bits allow the user to select an input channel as well as the input format. Depending on the PCB connections, only a subset of the INSEL modes are valid. The INSEL[3:0] does not only switch the analog input muxing, it also configures the standard definition processor core to process CVBS (Comp), S-Video (Y/C), or component (YPbPr) format.

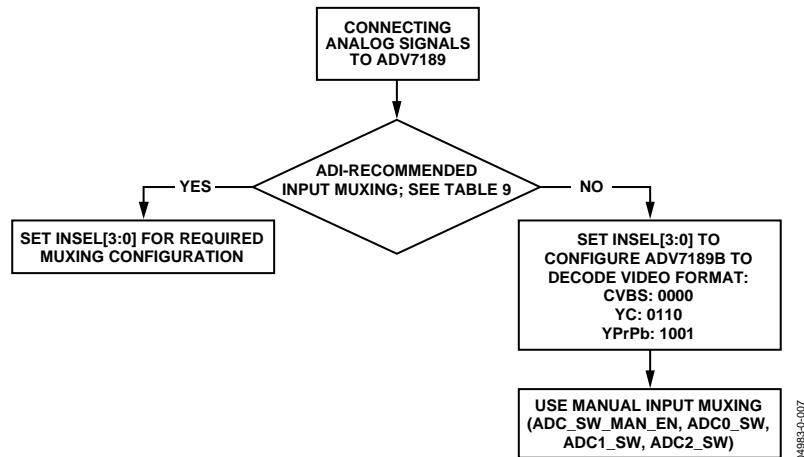

Figure 7. Input Muxing Overview

Table 8. Input Channel Switching Using INSEL[3:0]

INSEL[3:0]	Description	
	Analog Input Pins	Video Format
0000	CVBS1 = AIN1 (default)	Composite
0001	CVBS2 = AIN2	Composite

ADI-recommended input muxing is designed to minimize crosstalk between signal channels and to obtain the highest level of signal integrity. Table 9 summarizes how the PCB layout should connect analog video signals to the ADV7189B.

It is strongly recommended to connect any unused analog input pins to AGND to act as a shield.

Inputs AIN7 to AIN11 should be connected to AGND when only six input channels are used. This improves the quality of the sampling due to better isolation between channels.

AIN12 is not under the control of INSEL[3:0]. It can only be routed to ADC0/ADC1/ADC2 by manual muxing. See Table 10 for further details.

Manual Input Muxing

By accessing a set of manual override muxing registers, the analog input muxes of the ADV7189B can be controlled directly. This is referred to as manual input muxing.

Manual input muxing overrides other input muxing control bits, for example, INSEL. The manual muxing is activated by setting the ADC_SW_MAN_EN bit. It only affects the analog switches in front of the ADCs.

This means if the settings of INSEL and the manual input muxing registers (ADC0/1/2_sw) contradict each other, the ADC0/ADC1/ADC2_sw settings apply and INSEL is ignored.

Manual input muxing controls only the analog input muxes. INSEL[3:0] still has to be set so the follow-on blocks process the video data in the correct format.

This means INSEL must be used to tell the ADV7189B whether the input signal is of component, YC, or CVBS format.

Restrictions in the channel routing are imposed by the analog signal routing inside the IC; every input pin cannot be routed to each ADC. Refer to Figure 6 for an overview on the routing capabilities inside the chip. The three mux sections can be controlled by the reserved control signal buses ADC0/ADC1/ADC2_sw[3:0]. Table 10 explains the control words used.

SETADC_sw_man_en, Manual Input Muxing Enable, Address C4[7]

GLOBAL CONTROL REGISTERS

Register control bits listed in this section affect the whole chip.

POWER-SAVE MODES

Power-Down

PDBP, Address 0x0F[2]

The digital core of the ADV7189B can be shut down by using a pin ($\overline{\text{PWRDN}}$) and a bit ($\overline{\text{PWRDN}}$, see below). The PDBP controls which of the two has the higher priority. The default is to give the pin ($\overline{\text{PWRDN}}$) priority. This allows the user to have the ADV7189B powered down by default.

When PDBD is 0 (default), the digital core power is controlled by the $\overline{\text{PWRDN}}$ pin (the bit is disregarded).

When PDBD is 1, the bit has priority (the pin is disregarded).

PWRDN, Address 0x0F[5]

Setting the PWRDN bit switches the ADV7189B into a chip-wide power-down mode. The power down stops the clock from entering the digital section of the chip, thereby freezing its operation. No I²C bits are lost during power down. The PWRDN bit also affects the analog blocks and switches them into low current modes. The I²C interface itself is unaffected, and remains operational in power-down mode.

The ADV7189B leaves the power-down state if the PWRDN bit is set to 0 (via I²C), or if the overall part is reset using the $\overline{\text{RESET}}$ pin.

Note: PDBP must be set to 1 for the PWRDN bit to power down the ADV7189B.

When PWRDN is 0 (default), the chip is operational.

When PWRDN is 1, the ADV7189B is in chip-wide power down.

ADC Power-Down Control

The ADV7189B contains three 12-bit ADCs (ADC 0, ADC 1, and ADC 2). If required, it is possible to power down each ADC individually.

The ADCs should be powered down when in:

- CVBS mode. ADC 1 and ADC 2 should be powered down to save on power consumption.
- S-Video mode. ADC 2 should be powered down to save on power consumption.

PWRDN_ADC_0, Address 0x3A[3]

When PWRDN_ADC_0 is 0 (default), the ADC is in normal operation.

When PWRDN_ADC_0 is 1, ADC 0 is powered down.

PWRDN_ADC_1, Address 0x3A[2]

When PWRDN_ADC_1 is 0 (default), the ADC is in normal operation.

When PWRDN_ADC_1 is 1, ADC 1 is powered down.

PWRDN_ADC_2, Address 0x3A[1]

When PWRDN_ADC_2 is 0 (default), the ADC is in normal operation.

When PWRDN_ADC_2 is 1, ADC 2 is powered down.

RESET CONTROL

Chip Reset (RES), Address 0x0F[7]

Setting this bit, equivalent to controlling the $\overline{\text{RESET}}$ pin on the ADV7189B, issues a full chip reset. All I²C registers get reset to their default values. Note: Some register bits do not have a reset value specified. They keep their last written value. These bits are marked as having a reset value of x in the register table. After the reset sequence, the part immediately starts to acquire the incoming video signal.

After setting the RES bit, or initiating a reset via the pin, the part returns to the default mode of operation with respect to its primary mode of operation. All I²C bits are loaded with their default values, making this bit self-clearing.

Executing a software reset takes approximately 2 ms. However, it is recommended to wait 5 ms before any further I²C writes are performed.

The I²C master controller receives a no-acknowledge condition on the ninth clock cycle when chip reset is implemented. See the MPU Port Description section for a full description.

When RES is 0 (default), operation is normal.

When RES is 1, the reset sequence starts.

GLOBAL PIN CONTROL

Three-State Output Drivers

TOD, Address 0x03[6]

This bit allows the user to three-state the output drivers of the ADV7189B.

Upon setting the TOD bit, the P[19:0], HS, VS, FIELD, and SFL pins are three-stated.

The timing pins (HS/VS/FIELD) can be forced active via the TIM_OE bit. For more information on three-state control, refer to the Three-State LLC Drivers and the Timing Signals Output Enable sections.

Individual drive strength controls are provided via the DR_STR_XX bits.

The ADV7189B supports three-stating via a dedicated pin. When set high, the \overline{OE} pin three-states the output drivers for P[19:0], HS, VS, FIELD, and SFL. The output drivers are three-stated if the TOD bit or the \overline{OE} pin is set high.

When TOD is 0 (default), the output drivers are enabled.

When TOD is 1, the output drivers are three-stated.

Three-State LLC Drivers

TRI_LLC, Address 0x1D[7]

This bit allows the output drivers for the LLC1 pin and LLC2 pin of the ADV7189B to be three-stated. For more information on three-state control, refer to the Three-State Output Drivers and the Timing Signals Output Enable sections.

Individual drive strength controls are provided via the DR_STR_XX bits.

When TRI_LLC is 0 (default), the LLC pin drivers work according to the DR_STR_C[1:0] setting (pin enabled).

When TRI_LLC is 1, the LLC pin drivers are three-stated.

Timing Signals Output Enable

TIM_OE, Address 0x04[3]

The TIM_OE bit should be regarded as an addition to the TOD bit. Setting it high forces the output drivers for HS, VS, and FIELD into the active (that is, driving) state even if the TOD bit is set. If set to low, the HS, VS, and FIELD pins are three-stated dependent on the TOD bit. This functionality is useful if the decoder is to be used as a timing generator only. This may be the case if only the timing signals are to be extracted from an incoming signal, or if the part is in free-run mode where a separate chip can output, for instance, a company logo.

For more information on three-state control, refer to the Three-State Output Drivers and the Three-State LLC Drivers sections.

Individual drive strength controls are provided via the DR_STR_XX bits.

When TIM_OE is 0 (default), HS, VS, and FIELD are three-stated according to the TOD bit.

When TIM_OE is 1, HS, VS, and FIELD are forced active all the time.

Drive Strength Selection (Data)

DR_STR[1:0] Address 0xF4[5:4]

For EMC and crosstalk reasons, it can be desirable to strengthen or weaken the drive strength of the output drivers. The DR_STR[1:0] bits affect the P[19:0] output drivers.

For more information on three-state control, refer to the Drive Strength Selection (Clock) and the Drive Strength Selection (Sync) sections.

Table 11. DR_STR_C Function

DR_STR_C[1:0]	Description
00	Low drive strength (1×).
01 (default)	Medium low drive strength (2×).
10	Medium high drive strength (3×).
11	High drive strength (4×).

Drive Strength Selection (Clock)

DR_STR_C[1:0] Address 0xF4[3:2]

The DR_STR_C[1:0] bits can be used to select the strength of the clock signal output driver (LLC pin). For more information, refer to the Drive Strength Selection (Sync) and the Drive Strength Selection (Data) sections.

Table 12. DR_STR_C Function

DR_STR_C[1:0]	Description
00	Low drive strength (1×).
01 (default)	Medium low drive strength (2×).
10	Medium high drive strength (3×).
11	High drive strength (4×).

Drive Strength Selection (Sync)

DR_STR_S[1:0] Address 0xF4[1:0]

The DR_STR_S[1:0] bits allow the user to select the strength of the synchronization signals with which HS, VS, and F are driven. For more information, refer to the Drive Strength Selection (Clock) and the Drive Strength Selection (Data) sections.

Table 13. DR_STR_S Function

DR_STR_S[1:0]	Description
00	Low drive strength (1×).
01 (default)	Medium low drive strength (2×).
10	Medium high drive strength (3×).
11	High drive strength (4×).

Enable Subcarrier Frequency Lock Pin

EN_SFL_PIN Address 0x04[1]

The EN_SFL_PIN bit enables the output of subcarrier lock information (also known as GenLock) from the ADV7189B core to an encoder in a decoder-encoder back-to-back arrangement.

When EN_SFL_PIN is 0 (default), the subcarrier frequency lock output is disabled.

When EN_SFL_PIN is 1, the subcarrier frequency lock information is presented on the SFL pin.

Polarity LLC Pin

PCLK Address 0x37[0]

The polarity of the clock that leaves the ADV7189B via the LLC1 and LLC2 pins can be inverted using the PCLK bit.

Changing the polarity of the LLC clock output can be necessary to meet the setup-and-hold time expectations of follow-on chips.

Note: This bit also inverts the polarity of the LLC2 clock.

When PCLK is 0, the LLC output polarity is inverted.

When PCLK is 1 (default), the LLC output polarity is normal (as per the Timing Diagrams).

GLOBAL STATUS REGISTERS

Four registers provide summary information about the video decoder. The IDENT register allows the user to identify the revision code of the ADV7189B. The other three registers contain status bits from the ADV7189B.

IDENTIFICATION

IDENT[7:0] Address 0x11[7:0]

This register provides identification of the revision of the ADV7189B.

An identification value of 0x11 indicates the ADV7189, released silicon.

An identification value of 0x13 indicates the ADV7189B silicon.

STATUS 1

STATUS_1[7:0] Address 0x10[7:0]

This read-only register provides information about the internal status of the ADV7189B. These bits are used to set VS free run (coast) frequency. See the VS_Coast[1:0], Address 0xF9[3:2] section and COL[2:0] Count Out-of-Lock, Address 0x51[5:3] for information on the timing.

Depending on the setting of the FSCLE bit, the Status[0] and Status[1] are based solely on horizontal timing information or on the horizontal timing and lock status of the color subcarrier. See the FSCLE FSC Lock Enable, Address 0x51[7] section.

SD AUTODETECTION RESULT

AD_RESULT[2:0] Address 0x10[6:4]

The AD_RESULT[2:0] bits report back on the findings from the autodetection block. For more information on enabling the autodetection block, see the General Setup section. For information on configuring it, see the Autodetection of SD Modes section.

Table 14. AD_RESULT Function

AD_RESULT[2:0]	Description
000	NTSM-MJ
001	NTSC-443
010	PAL-M
011	PAL-60
100	PAL-BGHID
101	SECAM
110	PAL-Combination N
111	SECAM 525

Table 15. STATUS 1 Function

STATUS 1[7:0]	Bit Name	Description
0	IN_LOCK	In lock (right now).
1	LOST_LOCK	Lost lock (since last read of this register).
2	FSC_LOCK	F _{SC} locked (right now).
3	FOLLOW_PW	AGC follows peak white algorithm.
4	AD_RESULT.0	Result of autodetection.
5	AD_RESULT.1	Result of autodetection.
6	AD_RESULT.2	Result of autodetection.
7	COL_KILL	Color kill active.

STATUS 2

STATUS_2[7:0], Address 0x12[7:0]

Table 16. STATUS 2 Function

STATUS 2[7:0]	Bit Name	Description
0	MVCS DET	Detected Macrovision color striping.
1	MVCS T3	Macrovision color striping protection. Conforms to Type 3 if high, to Type 2 if low.
2	MV_PS DET	Detected Macrovision pseudo sync pulses.
3	MV_AGC DET	Detected Macrovision AGC pulses.
4	LL_NSTD	Line length is nonstandard.
5	FSC_NSTD	F _{SC} frequency is nonstandard.
6	Reserved	
7	Reserved	

STATUS 3

STATUS_3[7:0], Address 0x13[7:0]

Table 17. STATUS 3 Function

STATUS 3[7:0]	Bit Name	Description
0	INST_HLOCK	Horizontal lock indicator (instantaneous).
1	GEMD	Gemstar Detect.
2	SD_OP_50HZ	Flags whether 50 Hz or 60 Hz is present at output.
3		Reserved for future use.
4	FREE_RUN_ACT	ADV7189B outputs a blue screen (see the DEF_VAL_EN Default Value Enable, Address 0x0C[0] section).
5	STD_FLD_LEN	Field length is correct for currently selected video standard.
6	INTERLACED	Interlaced video detected (field sequence found).
7	PAL_SW_LOCK	Reliable sequence of swinging bursts detected.

STANDARD DEFINITION PROCESSOR (SDP)

Figure 8. Block Diagram of the Standard Definition Processor

A block diagram of the ADV7189B's standard definition processor (SDP) is shown in Figure 8.

The ADV7189B block can handle standard definition video in CVBS, YC, and YPrPb formats. It can be divided into a luminance and chrominance path. If the input video is of a composite type (CVBS), both processing paths are fed with the CVBS input.

SD LUMA PATH

The input signal is processed by the following blocks:

- **Digital Fine Clamp.** This block uses a high precision algorithm to clamp the video signal.
- **Luma Filter Block.** This block contains a luma decimation filter (YAA) with a fixed response, and some shaping filters (YSH) that have selectable responses.
- **Luma Gain Control.** The automatic gain control (AGC) can operate on a variety of different modes, including gain based on the depth of the horizontal sync pulse, peak white mode, and fixed manual gain.
- **Luma Resample.** To correct for line-length errors and dynamic line-length changes, the data is digitally resampled.
- **Luma 2D Comb.** The two-dimensional comb filter provides YC separation.
- **AV Code Insertion.** At this point, the decoded luma (Y) signal is merged with the retrieved chroma values. AV codes (as per ITU-R. BT-656) can be inserted.

SD CHROMA PATH

The input signal is processed by the following blocks:

- **Digital Fine Clamp.** This block uses a high precision algorithm to clamp the video signal.
- **Chroma Demodulation.** This block employs a color subcarrier (F_{sc}) recovery unit to regenerate the color subcarrier for any modulated chroma scheme. The demodulation block then performs an AM demodulation for PAL and NTSC and an FM demodulation for SECAM.
- **Chroma Filter Block.** This block contains a chroma decimation filter (CAA) with a fixed response, and some shaping filters (CSH) that have selectable responses.
- **Gain Control.** Automatic gain control (AGC) can operate on several different modes, including gain based on the color subcarrier's amplitude, gain based on the depth of the horizontal sync pulse on the luma channel, or fixed manual gain.
- **Chroma Resample.** The chroma data is digitally resampled to keep it perfectly aligned with the luma data. The resampling is done to correct for static and dynamic line-length errors of the incoming video signal.
- **Chroma 2D Comb.** The two-dimensional, 5-line, superadaptive comb filter provides high quality YC separation in case the input signal is CVBS.
- **AV Code Insertion.** At this point, the demodulated chroma (Cr and Cb) signal is merged with the retrieved luma values. AV codes (as per ITU-R. BT-656) can be inserted.

SYNC PROCESSING

The ADV7189B extracts syncs embedded in the video data stream. There is currently no support for external HS/VS inputs. The sync extraction has been optimized to support imperfect video sources such as VCRs with head switches. The actual algorithm used employs a coarse detection based on a threshold crossing followed by a more detailed detection using an adaptive interpolation algorithm. The raw sync information is sent to a line-length measurement and prediction block. The output of this is then used to drive the digital resampling section to ensure that the ADV7189B outputs 720 active pixels per line.

The sync processing on the ADV7189B also includes the following specialized postprocessing blocks that filter and condition the raw sync information retrieved from the digitized analog video.

- Vsync Processor. This block provides extra filtering of the detected Vsyncs to give improved vertical lock.
- Hsync Processor. The Hsync processor is designed to filter incoming Hsyncs that are corrupted by noise, providing much improved performance for video signals with stable time base but poor SNR.

VBI DATA RECOVERY

The ADV7189B can retrieve the following information from the input video:

- Wide-screen signaling (WSS)
- Copy generation management system (CGMS)
- Closed captioning (CC)
- Macrovision protection presence
- EDTV data
- Gemstar-compatible data slicing

The ADV7189B is also capable of automatically detecting the incoming video standard with respect to

- Color subcarrier frequency
- Field rate
- Line rate

The ADV7189B can configure itself to support PAL-BGHID, PAL-M/N, PAL-combination N, NTSC-M, NTSC-J, SECAM 50 Hz/60 Hz, NTSC4.43, and PAL60.

GENERAL SETUP

Video Standard Selection

The VID_SEL[3:0] register allows the user to force the digital core into a specific video standard. Under normal circumstances, this should not be necessary. The VID_SEL[3:0] bits default to an autodetection mode that supports PAL, NTSC, SECAM, and variants thereof. The following section provides more information on the autodetection system.

Autodetection of SD Modes

To guide the autodetect system of the ADV7189B, individual enable bits are provided for each of the supported video standards. Setting the relevant bit to 0 inhibits the standard from being detected automatically. Instead, the system picks the closest of the remaining enabled standards. The results of the autodetection can be read back via the status registers. See the Global Status Registers section for more information.

VID_SEL[3:0] Address 0x00[7:4]

Table 18. VID_SEL Function

VID_SEL[3:0]	Description
0000 (default)	Autodetect (PAL BGHID) <=> NTSC J (no pedestal), SECAM.
0001	Autodetect (PAL BGHID) <=> NTSC M (pedestal), SECAM.
0010	Autodetect (PAL N) (pedestal) <=> NTSC J (no pedestal), SECAM.
0011	Autodetect (PAL N) (pedestal) <=> NTSC M (pedestal), SECAM.
0100	NTSC J (1).
0101	NTSC M (1).
0110	PAL 60.
0111	NTSC 4.43 (1).
1000	PAL BGHID.
1001	PAL N[= PAL BGHID (with pedestal)].
1010	PAL M (without pedestal).
1011	PAL M.
1100	PAL Combination N.
1101	PAL Combination N (with pedestal).
1110	SECAM.
1111	SECAM (with pedestal).

AD_SEC525_EN Enable Autodetection of SECAM 525 Line Video, Address 0x07[7]

Setting AD_SEC525_EN to 0 (default), disables the autodetection of a 525-line system with a SECAM style, FM-modulated color component.

Setting AD_SEC525_EN to 1 enables the detection.

AD_SECAM_EN Enable Autodetection of SECAM, Address 0x07[6]

Setting AD_SECAM_EN to 0 disables the autodetection of SECAM.

Setting AD_SECAM_EN to 1 (default) enables the detection.

ADV7189B

AD_N443_EN Enable Autodetection of NTSC 443, Address 0x07[5]

Setting AD_N443_EN to 0 disables the autodetection of NTSC style systems with a 4.43 MHz color subcarrier.

Setting AD_N443_EN to 1 (default) enables the detection.

AD_P60_EN Enable Autodetection of PAL60, Address 0x07[4]

Setting AD_P60_EN to 0 disables the autodetection of PAL systems with a 60 Hz field rate.

Setting AD_P60_EN to 1 (default) enables the detection.

AD_PALN_EN Enable Autodetection of PAL N, Address 0x07[3]

Setting AD_PALN_EN to 0 disables the detection of the PAL N standard.

Setting AD_PALN_EN to 1 (default) enables the detection.

AD_PALM_EN Enable Autodetection of PAL M, Address 0x07[2]

Setting AD_PALM_EN to 0 disables the autodetection of PAL M.

Setting AD_PALM_EN to 1 (default), enables the detection.

AD_NTSC_EN Enable Autodetection of NTSC, Address 0x07[1]

Setting AD_NTSC_EN to 0 disables the detection of standard NTSC.

Setting AD_NTSC_EN to 1 (default) enables the detection.

AD_PAL_EN Enable Autodetection of PAL, Address 0x07[0]

Setting AD_PAL_EN to 0 disables the detection of standard PAL.

Setting AD_PAL_EN to 1 (default) enables the detection.

SFL_INV Subcarrier Frequency Lock Inversion

This bit controls the behavior of the PAL switch bit in the SFL (GenLock Telegram) data stream. It was implemented to solve some compatibility issues with video encoders. It solves two problems as follows:

First, the PAL switch bit is only meaningful in PAL. Some encoders (including Analog Devices encoders) also look at the state of this bit in NTSC.

Second, there was a design change in Analog Devices encoders from ADV717x to ADV719x. The older versions used the SFL (GenLock Telegram) bit directly, while the later ones invert the bit prior to using it. The reason for this is the inversion compensated for the 1-line delay of an SFL (GenLock Telegram) transmission.

As a result, ADV717x encoders need the PAL switch bit in the SFL (GenLock Telegram) to be 1 for NTSC to work. Also, ADV7190/ADV7191/ADV7194 encoders need the PAL switch bit in the SFL to be 0 to work in NTSC. If the state of the PAL switch bit is wrong, a 180° phase shift occurs.

In a decoder/encoder back-to-back system in which SFL is used, this bit must be set up properly for the specific encoder used.

SFL_INV Address 0x41[6]

Setting SFL_INV[6] to 0 makes the part SFL-compatible with ADV7190/ADV7191/ADV7194 encoders.

Setting SFL_INV to 1 (default) makes the part SFL-compatible with ADV717x/ADV7173x encoders.

Lock-Related Controls

Lock information is presented to the user through Bits[1:0] of the Status 1 register. See the STATUS_1[7:0] Address 0x10[7:0] section. Figure 9 outlines the signal flow and the controls available to influence the way the lock status information is generated.

SRLS Select Raw Lock Signal, Address 0x51[6]

Using the SRLS bit, the user can choose between two sources for determining the lock status (per Bits[1:0] in the Status 1 register).

- The time_win signal is based on a line-to-line evaluation of the horizontal synchronization pulse of the incoming video. It reacts quickly.
- The free_run signal evaluates the properties of the incoming video over several fields, and takes vertical synchronization information into account.

Setting SRLS to 0 (default) selects the free_run signal.

Setting SRLS to 1 selects the time_win signal.

FSCLE F_{SC} Lock Enable, Address 0x51[7]

The FSCLE bit allows the user to choose whether the status of the color subcarrier loop is taken into account when the overall lock status is determined and presented via Bits[1:0] in Status Register 1. This bit must be set to 0 when operating the ADV7189B in YPrPb component mode in order to generate a reliable HLOCK status bit.

Setting FSCLE to 0 (default) makes the overall lock status dependent on only the horizontal sync lock.

Setting FSCLE to 1 makes the overall lock status dependent on the horizontal sync lock and F_{SC} lock.

VS_Coast[1:0], Address 0xF9[3:2]

These bits are used to set VS free-run (coast) frequency.

Table 19. VS_COAST[1:0] Function

VS_COAST[1:0]	Description
00 (default)	Auto coast mode—follows VS frequency from last video input
01	Forces 50 Hz coast mode
10	Forces 60 Hz coast mode
11	Reserved

CIL[2:0] Count Into Lock, Address 0x51[2:0]

CIL[2:0] determines the number of consecutive lines for which the into lock condition must be true before the system switches into the locked state and reports this via Status 0[1:0]. It counts the value in lines of video.

Table 20. CIL Function

CIL[2:0]	Description
000	1
001	2
010	5
011	10
100 (default)	100
101	500
110	1000
111	100000

COL[2:0] Count Out-of-Lock, Address 0x51[5:3]

COL[2:0] determines the number of consecutive lines for which the out-of-lock condition must be true before the system switches into unlocked state, and reports this via Status 0[1:0]. It counts the value in lines of video.

Table 21. COL Function

COL[2:0]	Description
000	1
001	2
010	5
011	10
100 (default)	100
101	500
110	1000
111	100000

SD COLOR CONTROLS

These registers allow the user to control picture appearance including control of the active data in the event of video being lost. These controls are independent of any other controls. For instance, brightness control is independent from picture clamping, although both controls affect the signal's dc level.

CON[7:0] Contrast Adjust, Address 0x08[7:0]

This register allows the user to adjust the contrast of the picture.

Table 22. CON Function

CON[7:0]	Description
0x80 (default)	Gain on luma channel = 1
0x00	Gain on luma channel = 0
0xFF	Gain on luma channel = 2

SD_SAT_Cb[7:0] SD Saturation Cb Channel, Address 0xE3[7:0]

This register allows the user to control the gain of the Cb channel only. The user can adjust the saturation of the picture.

Table 23. SD_SAT_Cb Function

SD_SAT_Cb[7:0]	Description
0x80 (default)	Chroma gain = 0 dB
0x00	Gain on Cb channel = -42 dB
0xFF	Gain on Cb channel = +6 dB

ADV7189B

SD_SAT_Cr[7:0] SD Saturation Cr Channel, Address 0xE4[7:0]

This register allows the user to control the gain of the Cr channel only.

Table 24. SD_SAT_Cr Function

SD_SAT_Cr[7:0]	Description
0x80 (default)	Chroma gain = 0 dB
0x00	Gain on Cb channel = -42 dB
0xFF	Gain on Cb channel = +6 dB

SD_OFF_Cb[7:0] SD Offset Cb Channel, Address 0xE1[7:0]

This register allows the user to select an offset for data on the Cr channel only and adjust the hue of the picture. There is a functional overlap with the Hue[7:0] register.

Table 25. SD_OFF_Cb Function

SD_OFF_Cb[7:0]	Description
0x80 (default)	0 offset applied to the Cb channel
0x00	-312 mV offset applied to the Cb channel
0xFF	+312 mV offset applied to the Cb channel

SD_OFF_Cr[7:0] SD Offset Cr Channel, Address 0xE2[7:0]

This register allows the user to select an offset for data on the Cr channel only and adjust the hue of the picture. There is a functional overlap with the Hue[7:0] register.

Table 26. SD_OFF_Cr Function

SD_OFF_Cr[7:0]	Description
0x80 (default)	0 offset applied to the Cr channel
0x00	-312 mV offset applied to the Cr channel
0xFF	+312 mV offset applied to the Cr channel

BRI[7:0] Brightness Adjust, Address 0x0A[7:0]

This register controls the brightness of the video signal through the ADV7189B. It allows the user to adjust the brightness of the picture.

Table 27. BRI Function

BRI[7:0]	Description
0x00 (default)	Offset of the luma channel = 0IRE
0x7F	Offset of the luma channel = +100IRE
0xFF	Offset of the luma channel = -100IRE

HUE[7:0] Hue Adjust, Address 0x0B[7:0]

This register contains the value for the color hue adjustment. It allows the user to adjust the hue of the picture.

HUE[7:0] has a range of $\pm 90^\circ$, with 0x00 equivalent to an adjustment of 0° . The resolution of HUE[7:0] is 1 bit = 0.7° .

The hue adjustment value is fed into the AM color demodulation block. Therefore, it only applies to video signals that contain chroma information in the form of an AM modulated carrier (CVBS or Y/C in PAL or NTSC). It does not affect SECAM and does not work on component video inputs (YPrPb).

Table 28. HUE Function

HUE[7:0]	Description
0x00 (default)	Phase of the chroma signal = 0°
0x7F	Phase of the chroma signal = -90°
0x80	Phase of the chroma signal = $+90^\circ$

DEF_Y[5:0] Default Value Y, Address 0x0C[7:2]

When the ADV7189B loses lock on the incoming video signal or when there is no input signal, the DEF_Y[5:0] register allows the user to specify a default luma value to be output. This value is used under the following conditions:

- If DEF_VAL_AUTO_EN bit is set to high, and the ADV7189B lost lock to the input video signal. This is the intended mode of operation (automatic mode).
- The DEF_VAL_EN bit is set, regardless of the lock status of the video decoder. This is a forced mode that can be useful during configuration.

The DEF_Y[5:0] values define the 6 MSBs of the output video. The remaining LSBs are padded with 0s. For example, in 10-bit mode, the output is $Y[9:0] = \{\text{DEF_Y}[5:0], 0, 0, 0, 0\}$.

DEF_Y[5:0] is 0x0D (Blue) is the default value for Y.

Register 0x0C has a default value of 0x36.

DEF_C[7:0] Default Value C, Address 0x0D[7:0]

The DEF_C[7:0] register complements the DEF_Y[5:0] value. It defines the 4 MSBs of Cr and Cb values to be output if

- The DEF_VAL_AUTO_EN bit is set to high and the ADV7189B can't lock to the input video (automatic mode).
- DEF_VAL_EN bit is set to high (forced output).

The data that is finally output from the ADV7189B for the chroma side is $\text{Cr}[7:0] = \{\text{DEF_C}[7:4], 0, 0, 0, 0\}$, $\text{Cb}[7:0] = \{\text{DEF_C}[3:0], 0, 0, 0, 0\}$.

In full 10-bit output mode, two extra LSBs of value 00 are appended.

DEF_C[7:0] is 0x7C (blue) is the default value for Cr and Cb.

DEF_VAL_EN Default Value Enable, Address 0x0C[0]

This bit forces the use of the default values for Y, Cr, and Cb. Refer to the descriptions for DEF_Y and DEF_C for additional information. In this mode, the decoder also outputs a stable 27 MHz clock, HS, and VS.

Setting DEF_VAL_EN to 0 (default) outputs a colored screen determined by user-programmable Y, Cr, and Cb values when the decoder free-runs. Free-run mode is turned on and off by the DEF_VAL_AUTO_EN bit.

Setting DEF_VAL_EN to 1 forces a colored screen output determined by user-programmable Y, Cr, and Cb values. This overrides picture data even if the decoder is locked.

DEF_VAL_AUTO_EN Default Value Automatic Enable, Address 0x0C[1]

This bit enables the automatic use of the default values for Y, Cr, and Cb when the ADV7189B cannot lock to the video signal.

Setting DEF_VAL_AUTO_EN to 0 disables free-run mode. If the decoder is unlocked, it outputs noise.

Setting DEF_VAL_EN to 1 (default) enables free-run mode. A colored screen set by the user-programmable Y, Cr, and Cb values is displayed when the decoder loses lock.

CLAMP OPERATION

The input video is ac-coupled into the ADV7189B through a 0.1 μ F capacitor. The recommended range of the input video signal range be 0.5 V to 1.6 V (typically 1 V p-p). If the signal exceeds the range, it cannot be processed correctly in the decoder. Because the input is ac-coupled into the decoder, its dc value needs to be restored. This process is referred to as clamping the video. This section explains the general process of clamping on the ADV7189B and shows the different ways in which a user can configure its behavior.

The ADV7189B uses a combination of current sources and a digital processing block for clamping, as shown in Figure 10. The analog processing channel shown is replicated three times inside the IC. While only one single channel (and only one ADC) is needed for a CVBS signal, two independent channels are needed for YC (S-VHS) type signals, and three independent channels are needed to allow component signals (YPrPb) to be processed.

The clamping can be divided into two sections:

- Clamping before the ADC (analog domain): current sources.
- Clamping after the ADC (digital domain): digital processing block.

The ADCs can digitize an input signal only if it resides within the ADC's 1.6 V input voltage range. An input signal with a dc level that is too large or too small is clipped at the top or bottom of the ADC range.

The primary task of the analog clamping circuits is to ensure the video signal stays within the valid ADC input window, so the analog-to-digital conversion can take place. It is not necessary to clamp the input signal with a very high accuracy in the analog domain as long as the video signal fits the ADC range.

After digitization, the digital fine clamp block corrects for any remaining variations in dc level. Since the dc level of an input video signal refers directly to the brightness of the picture transmitted, it is important to perform a fine clamp with high accuracy; otherwise, brightness variations can occur. Dynamic changes in the dc level lead to visually objectionable artifacts so it is recommended not to use dynamic changes.

The clamping scheme has to complete two tasks. It must be able to acquire a newly connected video signal with a completely unknown dc level, and it must maintain the dc level during normal operation.

For quickly acquiring an unknown video signal, the large current clamps can be activated. It is assumed the amplitude of the video signal is of a nominal value at this point. Control of the coarse and fine current clamp parameters is performed automatically by the decoder.

Standard definition video signals may have excessive noise on them. In particular, CVBS signals transmitted by terrestrial broadcast and demodulated using a tuner usually show very large levels of noise (>100 mV). A voltage clamp is unsuitable for this type of video signal. Instead, the ADV7189B employs a set of four current sources that cause coarse (>0.5 mA) and fine (<0.1 mA) currents to flow into and away from the high impedance node that carries the video signal (see Figure 10).

Figure 10. Clamping Overview

ADV7189B

The following sections describe the I²C signals that can be used to influence the behavior of the clamping block on the ADV7189B.

CCLEN Current Clamp Enable, Address 0x14[4]

The current clamp enable bit allows the user to switch off the current sources in the analog front end altogether. This can be useful if the incoming analog video signal is clamped externally.

When CCLEN is 0, the current sources are switched off.

When CCLEN is 1 (default), the current sources are enabled.

DCT[1:0] Digital Clamp Timing, Address 0x15[6:5]

The clamp timing register determines the time constant of the digital fine clamp circuitry. It is important to realize that the digital fine clamp reacts very quickly because it is supposed to immediately correct any residual dc level error for the active line. The time constant of the digital fine clamp must be much quicker than the one from the analog blocks.

By default, the time constant of the digital fine clamp is adjusted dynamically to suit the currently connected input signal.

Table 29. DCT Function

DCT[1:0]	Description
00	Slow (TC = 1 sec)
01	Medium (TC = 0.5 sec)
10 (default)	Fast (TC = 0.1 sec)
11	Determined by the ADV7189B, depending on the I/P video parameters

DCFE Digital Clamp Freeze Enable, Address 0x15[4]

This register bit allows the user to freeze the digital clamp loop at any time. It is intended for users who would like to do their own clamping. Users should disable the current sources for analog clamping via the appropriate register bits, wait until the digital clamp loop settles, and then freeze it via the DCFE bit.

When DCFE is 0 (default), the digital clamp is operational.

When DCFE is 1, the digital clamp loop is frozen.

LUMA FILTER

Data from the digital fine clamp block is processed by three sets of filters. Note: The data format at this point is CVBS for CVBS input or luma only for Y/C and YPrPb input formats.

- Luma antialias filter (YAA). The ADV7189B receives video at a rate of 27 MHz. (In the case of 4× oversampled video, the ADCs sample at 54 MHz, and the first decimation is performed inside the DPP filters. Therefore, the data rate into the ADV7189B is always 27 MHz.) The ITU-R BT.601 recommends a sampling frequency of 13.5 MHz.

The luma antialias filter decimates the oversampled video using a high quality, linear phase, low-pass filter that preserves the luma signal while at the same time attenuating out-of-band components. The luma antialias filter (YAA) has a fixed response.

- Luma shaping filters (YSH). The shaping filter block is a programmable low-pass filter with a wide variety of responses. It can be used to selectively reduce the luma video signal bandwidth (needed prior to scaling, for example). For some video sources that contain high frequency noise, reducing the bandwidth of the luma signal improves visual picture quality. A follow-on video compression stage can work more efficiently if the video is low-pass filtered.

The ADV7189B has two responses for the shaping filter: one that is used for good quality CVBS, component, and S-VHS type sources, and a second for nonstandard CVBS signals.

The YSH filter responses also include a set of notches for PAL and NTSC. However, it is recommended to use the comb filters for YC separation.

- Digital resampling filter. This block is used to allow dynamic resampling of the video signal to alter parameters such as the time base of a line of video. Fundamentally, the resampler is a set of low-pass filters. The actual response is chosen by the system with no requirement for user intervention.

Figure 12 through Figure 15 show the overall response of all filters together. Unless otherwise noted, the filters are set into a typical wideband mode.

Y-Shaping Filter

For input signals in CVBS format, the luma shaping filters play an essential role in removing the chroma component from a composite signal. YC separation must aim for the best possible crosstalk reduction while still retaining as much bandwidth (especially on the luma component) as possible. High quality YC separation can be achieved by using the internal comb filters of the ADV7189B. Comb filtering, however, relies on the frequency relationship of the luma component (multiples of the video line rate) and the color subcarrier (F_{sc}). For good quality CVBS signals, this relationship is known; the comb filter algorithms can be used to separate out luma and chroma with high accuracy.

With nonstandard video signals, the frequency relationship may be disturbed, and the comb filters may not be able to remove all crosstalk artifacts in an optimum fashion without the assistance of the shaping filter block.

An automatic mode for Y-shaped filtering is provided. In this mode, the ADV7189B evaluates the quality of the incoming video signal and selects the filter responses in accordance with the signal quality and video standard. YFSM, WYSFMOVR, and WYSFM allow the user to manually override these automatic decisions in part or in full.

The luma shaping filter has three control registers:

- YFSM[4:0] allows the user to manually select a shaping filter mode (applied to all video signals) or to enable an automatic selection (dependent on video quality and video standard).
- WYSFMOVR allows the user to manually override the WYSFM decision.
- WYSFM[4:0] allows the user to select a different shaping filter mode for good quality CVBS, component (YPrPb), and S-VHS (YC) input signals.

In automatic mode, the system preserves the maximum possible bandwidth for good CVBS sources (since they can successfully be combed) as well as for luma components of YPrPb and YC sources, since they need not be combed. For poor quality signals, the system selects from a set of proprietary shaping filter responses that complements comb filter operation in order to reduce visual artifacts. The decisions of the control logic are shown in Figure 11.

YFSM[4:0] Y-Shaping Filter Mode, Address 0x17[4:0]

The Y-shaping filter mode bits allow the user to select from a wide range of low-pass and notch filters. When switched in automatic mode, the filter is selected based on other register selections, for example, detected video standard, as well as properties extracted from the incoming video itself, for example, quality, time base stability. The automatic selection always picks the widest possible bandwidth for the video input encountered.

- If the YFSM settings specify a filter (that is, YFSM is set to values other than 00000 or 00001), the chosen filter is applied to all video, regardless of its quality.
- In automatic selection mode, the notch filters are only used for bad quality video signals. For all other video signals, wide band filters are used.

WYSFMOVR Wideband Y-Shaping Filter Override, Address 0x18[7]

Setting the WYSFMOVR bit enables the use of the WYSFM[4:0] settings for good quality video signals. For more information, refer to the general discussion of the luma-shaping filters in the Y-Shaping Filter section and the flowchart shown in Figure 11.

When WYSFMOVR is 0, the shaping filter for good quality video signals is selected automatically.

Setting WYSFMOVR to 1 (default) enables manual override via WYSFM[4:0].

WYSFM[4:0] Wide Band Y-Shaping Filter Mode, Address 0x18[4:0]

The WYSFM[4:0] bits allow the user to manually select a shaping filter for good quality video signals, for example, CVBS with stable time base, luma component of YPrPb, luma component of YC. The WYSFM bits are only active if the WYSFMOVR bit is set to 1. See the general discussion of the shaping filter settings in the Y-Shaping Filter section.

Figure 13. Y S-VHS 18 Extra Wideband Filter (CCIR 601 Compliant)

Figure 14. PAL Notch Filter Response

Figure 15. NTSC Notch Filter Response

CHROMA FILTER

Data from the digital fine clamp block is processed by three sets of filters. Note: the data format at this point is CVBS for CVBS inputs, or chroma only for Y/C or Cr/Cb interleaved for YCrCb input formats.

- Chroma Antialias Filter (CAA). The ADV7189B oversamples the CVBS by a factor of 2 and the Chroma/UV by a factor of 4. A decimating filter (CAA) is used to preserve the active video band and to remove any out-of-band components. The CAA filter has a fixed response.
- Chroma Shaping Filters (CSH). The shaping filter block can be programmed to perform a variety of low-pass responses. It can be used to selectively reduce the bandwidth of the chroma signal for scaling or compression.
- Digital Resampling Filter. This block is used to allow dynamic resampling of the video signal to alter parameters such as the time base of a line of video. Fundamentally, the resampler is a set of low-pass filters. The actual response is chosen by the system without user intervention.

The plots in Figure 16 show the overall response of all filters together.

CSFM[2:0] C-Shaping Filter Mode, Address 0x17[7]

The C-shaping filter mode bits allow the user to select from a range of low-pass filters, SH1 to SH5, and wideband mode for the chrominance signal. The auto-selection options automatically select from the filter options to give the specified response. (See settings 000 and 001 in Table 32).

Figure 16 shows the responses of SH1 (narrowest) to SH5 (widest) in addition to the wideband mode.

GAIN OPERATION

The gain control within the ADV7189B is done on a purely digital basis. The input ADCs support a 12-bit range, mapped into a 1.6 V analog voltage range. Gain correction takes place after the digitization in the form of a digital multiplier.

Advantages of this architecture over the commonly used programmable gain amplifier (PGA) before the ADCs include the fact that the gain is now completely independent of supply, temperature, and process variations.

As shown in Figure 17, the ADV7189B can decode a video signal as long as it fits into the ADC window. The two components to this are the amplitude of the input signal and the dc level it resides on. The dc level is set by the clamping circuitry (see the Clamp Operation section).

If the amplitude of the analog video signal is too high, clipping can occur, resulting in visual artifacts. The analog input range of the ADC, together with the clamp level, determines the maximum supported amplitude of the video signal.

The minimum supported amplitude of the input video is determined by the ADV7189B's ability to retrieve horizontal and vertical timing and to lock to the colorburst, if present.

There are separate gain control units for luma and chroma data. Both can operate independently of each other. The chroma unit, however, can also take its gain value from the luma path.

The possible AGC modes are summarized in Table 33.

It is possible to freeze the automatic gain control loops. This causes the loops to stop updating, and the AGC determined gain at the time of the freeze to stay active until the loop is either unfrozen or the gain mode of operation is changed.

The currently active gain from any of the modes can be read back. Refer to the description of the dual-function manual gain registers, LG[11:0] Luma Gain and CG[11:0] Chroma Gain, in the Luma Gain and the Chroma Gain sections.

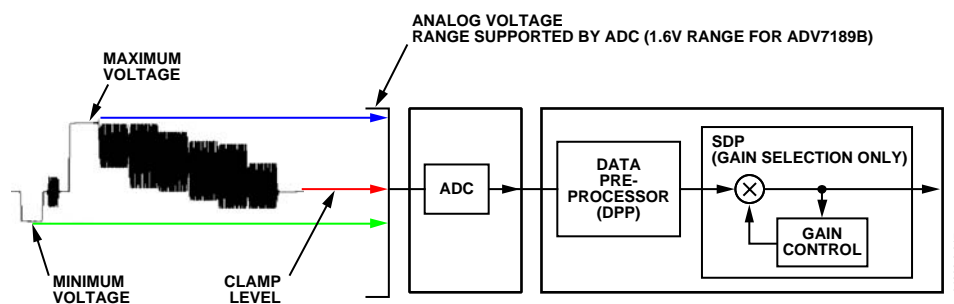

Figure 17. Gain Control Overview

Table 33. AGC Modes

Input Video Type	Luma Gain	Chroma Gain
Any	Manual gain luma.	Manual gain chroma.
CVBS	Dependent on horizontal sync depth. Peak White.	Dependent on color burst amplitude. Taken from luma path. Dependent on color burst amplitude. Taken from luma path.
Y/C	Dependent on horizontal sync depth. Peak White.	Dependent on color burst amplitude. Taken from luma path. Dependent on color burst amplitude. Taken from luma path.
YPrPb	Dependent on horizontal sync depth.	Taken from luma path.

Luma Gain**LAGC[2:0] Luma Automatic Gain Control, Address 0x2C[7:0]**

The luma automatic gain control mode bits select the mode of operation for the gain control in the luma path. There are ADI internal parameters to customize the peak white gain control. Contact ADI sales for more information.

Table 34. LAGC Function

LAGC[2:0]	Description
000	Manual fixed gain (use LMG[11:0])
001	AGC (blank level to sync tip); peak white algorithm off
010 (default)	AGC (blank level to sync tip); peak white algorithm on
011	Reserved
100	Reserved
101	Reserved
110	Reserved
111	Freeze gain

LAGT[1:0] Luma Automatic Gain Timing, Address 0x2F[7:6]

The luma automatic gain timing register allows the user to influence the tracking speed of the luminance automatic gain control. Note this register only has an effect if the LAGC[2:0] register is set to 001, 010, 011, or 100 (automatic gain control modes).

If peak white AGC is enabled and active (see the STATUS_1[7:0] Address 0x10[7:0] section), the actual gain update speed is dictated by the peak white AGC loop and, as a result, the LAGT settings have no effect. As soon as the part leaves peak white AGC, LAGT becomes relevant again.

The update speed for the peak white algorithm can be customized by the use of internal parameters. Contact ADI for more information.

Table 35. LAGT Function

LAGT[1:0]	Description
00	Slow (TC = 2 sec)
01	Medium (TC = 1 sec)
10	Fast (TC = 0.2 sec)
11 (default)	Adaptive

LG[11:0] Luma Gain, Address 0x2F[3:0]; Address 0x30[7:0]; LMG[11:0] Luma Manual Gain, Address 0x2F[3:0]; Address 0x30[7:0]

Luma Gain[11:0] is a dual-function register. If written to, a desired manual luma gain can be programmed. This gain becomes active if the LAGC[2:0] mode is switched to manual fixed gain. Equation 1 shows how to calculate a desired gain. If read back, this register returns the current gain value. Depending on the setting in the LAGC[2:0] bits, this is one of the following values:

- Luma manual gain value (LAGC[2:0] set to luma manual gain mode)
- Luma automatic gain value (LAGC[2:0] set to any of the automatic modes)

Table 36. LG/LMG Function

LG[11:0]/LMG[11:0]	Read/Write	Description
LMG[11:0] = X	Write	Manual gain for luma path
LG[11:0]	Read	Actually used gain

$$Luma_Gain = \frac{(0 < LG \leq 4095)}{2048} = 0...2 \quad (1)$$

ADV7189B

For example, program the ADV7189B into manual fixed gain mode with a desired gain of 0.89:

1. Use Equation 1 to convert the gain:
 $0.89 \times 2048 = 1822.72$
2. Truncate to integer value:
 $1822.72 = 1822$
3. Convert to hexadecimal:
 $1822d = 0x71E$
4. Split into two registers and program:
Luma Gain Control 1[3:0] = 0x7
Luma Gain Control 2[7:0] = 0x1E
5. Enable Manual Fixed Gain Mode:
Set LAGC[2:0] to 000

BETACAM Enable Betacam Levels, Address 0x01[5]

If YPrPb data is routed through the ADV7189B, the automatic gain control modes can target different video input levels, as outlined in. Note the BETACAM bit is valid only if the input mode is YPrPb (component). The BETACAM bit sets the target value for AGC operation. A review of the following sections is useful.

- INSEL[3:0] Input Selection, Address 0x00[3:0] to find out how component video (YPrPb) can be routed through the ADV7189B.
- Video Standard Selection to select the various standards, for example, with and without pedestal.

The automatic gain control (AGC) algorithms adjust the levels based on the setting of the BETACAM bit. See Table 37.

Table 37. BETACAM Function

BETACAM	Description
0 (default)	Assuming YPrPb is selected as input format. Selecting PAL with pedestal selects MII. Selecting PAL without pedestal selects SMPTE. Selecting NTSC with pedestal selects MII. Selecting NTSC without pedestal selects SMPTE.
1	Assuming YPrPb is selected as input format. Selecting PAL with pedestal selects BETACAM. Selecting PAL without pedestal selects BETACAM variant. Selecting NTSC with pedestal selects BETACAM. Selecting NTSC without pedestal selects BETACAM variant.

Table 38. Betacam Levels

Name	Betacam (mV)	Betacam Variant (mV)	SMPTE (mV)	III (mV)
Y Range	0 to 714 (incl. 7.5% pedestal)	0 to 714	0 to 700	0 to 700 (incl. 7.5% pedestal)
U and V Range	–467 to +467	–505 to +505	–350 to +350	–324 to +324
Sync Depth	286	286	300	300

PW_UPD Peak White Update, Address 0x2B[0]

The peak white and average video algorithms determine the gain based on measurements taken from the active video. The PW_UPD bit determines the rate of gain change. LAGC[2:0] must be set to the appropriate mode to enable the peak white or average video mode in the first place. For more information, refer to the LAGC[2:0] Luma Automatic Gain Control, Address 0x2C[7:0] section.

Setting PW_UPD to 0 updates the gain once per video line.

Setting PW_UPD to 1 (default) updates the gain once per field.

Chroma Gain

CAGC[1:0] Chroma Automatic Gain Control, Address 0x2C[1:0]

The two bits of color automatic gain control mode select the basic mode of operation for automatic gain control in the chroma path.

Table 39. CAGC Function

CAGC[1:0]	Description
00	Manual fixed gain (use CMG[11:0]).
01	Use luma gain for chroma.
10 (default)	Automatic gain (based on color burst).
11	Freeze chroma gain.

CAGT[1:0] Chroma Automatic Gain Timing, Address 0x2D[7:6]

The chroma automatic gain timing register allows the user to influence the tracking speed of the chroma automatic gain control. This register has an effect only if the CAGC[1:0] register is set to 10 (automatic gain).

Table 40. CAGT Function

CAGT[1:0]	Description
00	Slow (TC = 2 sec)
01	Medium (TC = 1 sec)
10	Fast (TC = 0.2 sec)
11 (default)	Adaptive

**CG[11:0] Chroma Gain, Address 0x2D[3:0];
Address 0x2E[7:0]; CMG[11:0] Chroma Manual Gain,
Address 0x2D[3:0]; Address 0x2E[7:0]**

Chroma Gain[11:0] is a dual-function register. If written to, a desired manual chroma gain can be programmed. This gain becomes active if the CAGC[1:0] mode is switched to manual fixed gain. Refer to Equation 2 for calculating a desired gain. If read back, this register returns the current gain value. Depending on the setting in the CAGC[1:0] bits, this is either

- Chroma manual gain value (CAGC[1:0] set to chroma manual gain mode)
- Chroma automatic gain value (CAGC[1:0] set to any of the automatic modes)

Table 41. CG/CMG Function

CG[11:0]/CMG[11:0]	Read/Write	Description
CMG[11:0]	Write	Manual gain for chroma path.
CG[11:0]	Read	Currently active gain.

$$\text{Chroma_Gain} = \frac{(0 < CG \leq 4095)}{1024} = 0...4 \quad (2)$$

For example, freezing the automatic gain loop and reading back the CG[11:0] register results in a value of 0x47A.

1. Convert the readback value to decimal
0x47A = 1146d
2. Apply Equation 2 to convert the readback value
1146/1024 = 1.12

CKE Color Kill Enable, Address 0x2B[6]

The color kill enable bit allows the optional color kill function to be switched on or off.

For QAM-based video standards (PAL and NTSC) as well as FM-based systems (SECAM), the threshold for the color kill decision is selectable via the CKILLTHR[2:0] bits.

If color kill is enabled and if the color carrier of the incoming video signal is less than the threshold for 128 consecutive video lines, color processing is switched off (black and white output). To switch the color processing back on, another 128 consecutive lines with a color burst greater than the threshold are required.

The color kill option only works for input signals with a modulated chroma part. For component input (YPrPb), there is no color kill.

Setting CKE to 0 disables color kill.

Setting CKE to 1 (default), enables color kill.

CKILLTHR[2:0] Color Kill Threshold, Address 0x3D[6:4]

The CKILLTHR[2:0] bits allow the user to select a threshold for the color kill function. The threshold applies to only QAM-based (NTSC and PAL) or FM-modulated (SECAM) video standards.

To enable the color kill function, the CKE bit must be set. For settings 000, 001, 010, and 011, chroma demodulation inside the ADV7189B may not work satisfactorily for poor input video signals.

Table 42. CKILLTHR Function

CKILLTHR[2:0]	Description	
	SECAM	NTSC, PAL
000	No color kill.	Kill at < 0.5%
001	Kill at < 5%.	Kill at < 1.5%
010	Kill at < 7%.	Kill at < 2.5%
011	Kill at < 8%.	Kill at < 4.0%
100 (default)	Kill at < 9.5%.	Kill at < 8.5% (default)
101	Kill at < 15%.	Kill at < 16.0%
110	Kill at < 32%.	Kill at < 32.0%
111	Reserved for ADI internal use only. Do not select.	

CHROMA TRANSIENT IMPROVEMENT (CTI)

The signal bandwidth allocated for chroma is typically much smaller than that of luminance. In the past, this was a valid way to fit a color video signal into a given overall bandwidth because the human eye is less sensitive to chrominance than to luminance.

The uneven bandwidth, however, can lead to visual artifacts in sharp color transitions. At the border of two bars of color, both components (luma and chroma) change at the same time (see Figure 18). Due to the higher bandwidth, the signal transition of the luma component is usually a lot sharper than that of the chroma component. The color edge is not sharp but is blurred, in the worst case, over several pixels.

Figure 18. CTI Luma/Chroma Transition

The chroma transient improvement block examines the input video data. It detects transitions of chroma, and can be programmed to “steepen” the chroma edges in an attempt to artificially restore lost color bandwidth. The CTI block, however, operates only on edges above a certain threshold to ensure that noise is not emphasized. Care has also been taken to ensure that edge ringing and undesirable saturation or hue distortion are avoided.

Chroma transient improvements are needed primarily for signals that experienced severe chroma bandwidth limitation. For those types of signals, it is strongly recommended to enable the CTI block via CTI_EN.

CTI_EN Chroma Transient Improvement Enable, Address 0x4D[0]

The CTI_EN bit enables the CTI function. If set to 0, the CTI block is inactive and the chroma transients are left untouched.

Setting CTI_EN to 0 disables the CTI block.

Setting CTI_EN to 1 (default) enables the CTI block.

CTI_AB_EN Chroma Transient Improvement Alpha Blend Enable, Address 0x4D[1]

The CTI_AB_EN bit enables an alpha-blend function within the CTI block. If set to 1, the alpha blender mixes the transient improved chroma with the original signal. The sharpness of the alpha blending can be configured via the CTI_AB[1:0] bits.

For the alpha blender to be active, the CTI block must be enabled via the CTI_EN bit.

Setting CTI_AB_EN to 0 disables the CTI alpha blender.

Setting CTI_AB_EN to 1 (default) enables the CTI alpha-blend mixing function.

CTI_AB[1:0] Chroma Transient Improvement Alpha Blend, Address 0x4D[3:2]

The CTI_AB[1:0] controls the behavior of alpha-blend circuitry that mixes the sharpened chroma signal with the original one. It thereby controls the visual impact of CTI on the output data.

For CTI_AB[1:0] to become active, the CTI block must be enabled via the CTI_EN bit, and the alpha blender must be switched on via CTI_AB_EN.

Sharp blending maximizes the effect of CTI on the picture, but can also increase the visual impact of small amplitude, high frequency chroma noise.

Table 43. CTI_AB Function

CTI_AB[1:0]	Description
00	Sharpest mixing between sharpened and original chroma signal.
01	Sharp mixing.
10	Smooth mixing.
11 (default)	Smoothest alpha blend function.

CTI_C_TH[7:0] CTI Chroma Threshold, Address 0x4E[7:0]

The CTI_C_TH[7:0] value is an unsigned, 8-bit number specifying how big the amplitude step in a chroma transition is to be steepened by the CTI block. Programming a small value into this register causes even smaller edges to be steepened by the CTI block. Making CTI_C_TH[7:0] a large value causes the block to only improve large transitions.

The default value for CTI_C_TH[7:0] is 0x08, indicating the threshold for the chroma edges prior to CTI.

DIGITAL NOISE REDUCTION (DNR)

Digital noise reduction is based on the assumption that high frequency signals with low amplitude are probably noise and their removal, therefore, improves picture quality.

DNR_EN Digital Noise Reduction Enable, Address 0x4D[5]

The DNR_EN bit enables the DNR block or bypasses it.

Setting DNR_EN to 0 bypasses DNR (disables it).

Setting DNR_EN to 1 (default) enables digital noise reduction on the luma data.

DNR_TH[7:0] DNR Noise Threshold, Address 0x50[7:0]

The DNR_TH[7:0] value is an unsigned 8-bit number used to determine the maximum edge that is interpreted as noise and therefore blanked from the luma data. Programming a large value into DNR_TH[7:0] causes the DNR block to interpret even large transients as noise and remove them. The effect on the video data is, therefore, more visible.

Programming a small value causes only small transients to be seen as noise and to be removed.

The recommended DNR_TH[7:0] setting for A/V inputs is 0x04, and the recommended DNR_TH[7:0] setting for tuner inputs is 0x0A.

The default value for DNR_TH[7:0] is 0x08, indicating the threshold for maximum luma edges to be interpreted as noise.

COMB FILTERS

The comb filters of the ADV7189B have been greatly improved to automatically handle video of all types, standards, and levels of quality. The NTSC and PAL configuration registers allow the user to customize comb filter operation, depending on which video standard is detected (by autodetection) or selected (by manual programming). In addition to the bits listed in this section, there are some further ADI internal controls; contact ADI sales for more information.

NTSC Comb Filter Settings

Used for NTSC-M/J CVBS inputs.

NSFSEL[1:0] Split Filter Selection NTSC, Address 0x19[3:2]

The NSFSEL[1:0] control selects how much of the overall signal bandwidth is fed to the combs. A narrow split filter selection gives better performance on diagonal lines, but leaves more dot crawl in the final output image. The opposite is true for selecting a wide bandwidth split filter.

Table 44. NSFSEL Function

NSFSEL[1:0]	Description
00 (default)	Narrow
01	Medium
10	Medium
11	Wide

CTAPSN[1:0] Chroma Comb Taps NTSC, Address 0x38[7:6]**Table 45. CTAPSN Function**

CTAPSN[1:0]	Description
00	Do not use.
01	NTSC chroma comb adapts 3 lines (3 taps) to 2 lines (2 taps).
10 (default)	NTSC chroma comb adapts 5 lines (5 taps) to 3 lines (3 taps).
11	NTSC chroma comb adapts 5 lines (5 taps) to 4 lines (4 taps).

CCMN[2:0] Chroma Comb Mode NTSC, Address 0x38[5:3]

Table 46. CCMN Function

CCMN[2:0]	Description	Configuration
0xx (default)	Adaptive comb mode.	Adaptive 3-line chroma comb for CTAPSN = 01. Adaptive 4-line chroma comb for CTAPSN = 10. Adaptive 5-line chroma comb for CTAPSN = 11.
100	Disable chroma comb.	
101	Fixed chroma comb (top lines of line memory).	Fixed 2-line chroma comb for CTAPSN = 01. Fixed 3-line chroma comb for CTAPSN = 10. Fixed 4-line chroma comb for CTAPSN = 11.
110	Fixed chroma comb (all lines of line memory).	Fixed 3-line chroma comb for CTAPSN = 01. Fixed 4-line chroma comb for CTAPSN = 10. Fixed 5-line chroma comb for CTAPSN = 11.
111	Fixed chroma comb (bottom lines of line memory).	Fixed 2-line chroma comb for CTAPSN = 01. Fixed 3-line chroma comb for CTAPSN = 10. Fixed 4-line chroma comb for CTAPSN = 11.

YCMN[2:0] Luma Comb Mode NTSC, Address 0x38[2:0]

Table 47. YCMN Function

YCMN[2:0]	Description	Configuration
0xx (default)	Adaptive comb mode.	Adaptive 3-line (3 taps) luma comb.
100	Disable luma comb.	Use low-pass/notch filter; see the Y-Shaping Filter section.
101	Fixed luma comb (top lines of line memory).	Fixed 2-line (2 taps) luma comb.
110	Fixed luma comb (all lines of line memory).	Fixed 3-line (3 taps) luma comb.
111	Fixed luma comb (bottom lines of line memory).	Fixed 2-line (2 taps) luma comb.

PAL Comb Filter Settings

Used for PAL-B/G/H/I/D, PAL-M, PAL-Combinational N, PAL-60, and NTSC443 CVBS inputs.

PSFSEL[1:0] Split Filter Selection PAL, Address 0x19[1:0]

The PSFSEL[1:0] control selects how much of the overall signal bandwidth is fed to the combs. A wide split filter selection eliminates dot crawl, but shows imperfections on diagonal lines. The opposite is true for selecting a narrow bandwidth split filter.

Table 48. PSFSEL Function

PSFSEL[1:0]	Description
00	Narrow
01 (default)	Medium
10	Wide
11	Widest

CTAPSP[1:0] Chroma Comb Taps PAL, Address 0x39[7:6]

Table 49. CTAPSP Function

CTAPSP[1:0]	Description
00	Do not use.
01	PAL chroma comb adapts 5 lines (3 taps) to 3 lines (2 taps); cancels cross luma only.
10	PAL chroma comb adapts 5 lines (5 taps) to 3 lines (3 taps); cancels cross luma and hue error less well.
11 (default)	PAL chroma comb adapts 5 lines (5 taps) to 4 lines (4 taps); cancels cross luma and hue error well.

CCMP[2:0] Chroma Comb Mode PAL, Address 0x39[5:3]

Table 50. CCMP Function

CCMP[2:0]	Description	Configuration
0xx (default)	Adaptive comb mode.	Adaptive 3-line chroma comb for CTAPSP = 01. Adaptive 4-line chroma comb for CTAPSP = 10. Adaptive 5-line chroma comb for CTAPSP = 11.
100	Disable chroma comb.	
101	Fixed chroma comb (top lines of line memory).	Fixed 2-line chroma comb for CTAPSP = 01. Fixed 3-line chroma comb for CTAPSP = 10. Fixed 4-line chroma comb for CTAPSP = 11.
110	Fixed chroma comb (all lines of line memory).	Fixed 3-line chroma comb for CTAPSP = 01. Fixed 4-line chroma comb for CTAPSP = 10. Fixed 5-line chroma comb for CTAPSP = 11.
111	Fixed chroma comb (bottom lines of line memory).	Fixed 2-line chroma comb for CTAPSP = 01. Fixed 3-line chroma comb for CTAPSP = 10. Fixed 4-line chroma comb for CTAPSP = 11.

YCMP[2:0] Luma Comb Mode PAL, Address 0x39[2:0]

Table 51. YCMP Function

YCMP[2:0]	Description	Configuration
0xx (default)	Adaptive comb mode.	Adaptive 5 lines (3 taps) luma comb.
100	Disable luma comb.	Use low-pass/notch filter, see the Y-Shaping Filter section.
101	Fixed luma comb (top lines of line memory).	Fixed 3 lines (2 taps) luma comb.
110	Fixed luma comb (all lines of line memory).	Fixed 5 lines (3 taps) luma comb.
111	Fixed luma comb (bottom lines of line memory).	Fixed 3 lines (2 taps) luma comb.

AV CODE INSERTION AND CONTROLS

This section describes the I²C-based controls that affect:

- Insertion of AV codes into the data stream.
- Data blanking during the vertical blank interval (VBI).
- The range of data values permitted in the output data stream.
- The relative delay of luma vs. chroma signals.

Note: Some of the decoded VBI data is being inserted during the horizontal blanking interval. See the Gemstar Data Recovery section for more information.

BT656-4 ITU Standard BT-R.656-4 Enable, Address 0x04[7]

The ITU has changed the position for toggling of the V bit within the SAV EAV codes for NTSC between Revisions 3 and Revision 4. The BT656-4 standard bit allows the user to select an output mode that is compliant with either the previous or the new standard. For further information, review the standard at www.itu.int.

Note the standard change affects NTSC only, and has no bearing on PAL.

When BT656-4 is 0 (default), the BT656-3 specification is used. The V bit goes low at EAV of Lines 10 and 273.

When BT656-4 is 1, the BT656-4 specification is used. The V bit goes low at EAV of Lines 20 and 283.

SD_DUP_AV Duplicate AV Codes, Address 0x03[0]

Depending on the output interface width, it can be necessary to duplicate the AV codes from the luma path into the chroma path.

In an 8-/10-bit-wide output interface (Cb/Y/Cr/Y interleaved data), the AV codes are defined as FF/00/00/AV, with AV being the transmitted word that contains information about H/V/F.

In this output interface mode, the following assignment takes place: Cb = FF, Y = 00, Cr = 00, and Y = AV.

In a 16-/20-bit output interface where Y and Cr/Cb are delivered via separate data buses, the AV code is over the whole 16/20 bits. The SD_DUP_AV bit allows the user to replicate the AV codes on both busses, so the full AV sequence can be found on the Y bus as well as on the Cr/Cb bus. See Figure 19.

When SD_DUP_AV is 0 (default), the AV codes are in single fashion (to suit 8-/10-bit interleaved data output).

When SD_DUP_AV is 1, the AV codes are duplicated (for 16-/20-bit interfaces).

VBI_EN Vertical Blanking Interval Data Enable, Address 0x03[7]

The VBI enable bit allows data such as intercast and closed-caption data to be passed through the luma channel of the decoder with a minimal amount of filtering. All data for Line 1 to Line 21 is passed through and available at the output port. The ADV7189B does not blank the luma data, and automatically switches all filters along the luma data path into their widest bandwidth. For active video, the filter settings for YSH and YPK are restored.

Refer to the BL_C_VBI Blank Chroma during VBI section for information on the chroma path.

When VBI_EN is 0 (default), all video lines are filtered/scaled.

When VBI_EN is 1, only the active video region is filtered/scaled.

Figure 19. AV Code Duplication Control

BL_C_VBI Blank Chroma During VBI, Address 0x04[2]

Setting BL_C_VBI high, the Cr and Cb values of all VBI lines are blanked. This is done so any data that may arrive during VBI is not decoded as color and output through Cr and Cb. As a result, it is possible to send VBI lines into the decoder, then output them through an encoder again, undistorted. Without this blanking, any wrongly decoded color is encoded by the video encoder; therefore, the VBI lines are distorted.

Setting BL_C_VBI to 0 decodes and outputs color during VBI.

Setting BL_C_VBI to 1 (default) blanks Cr and Cb values during VBI.

RANGE Range Selection, Address 0x04[0]

AV codes (as per ITU-R BT-656, formerly known as CCIR-656) consist of a fixed header made up of 0xFF and 0x00 values. These two values are reserved and are not to be used for active video. Additionally, the ITU specifies that the nominal range for video should be restricted to values between 16 and 235 for luma and 16 to 240 for chroma.

The RANGE bit allows the user to limit the range of values output by the ADV7189B to the recommended value range. This bit ensures the reserved values of 255d (0xFF) and 00d (0x00) are not presented on the output pins unless they are part of an AV code header.

Table 52. RANGE Function

RANGE	Description	
0	$16 \leq Y \leq 235$	$16 \leq C/P \leq 240$
1 (default)	$1 \leq Y \leq 254$	$1 \leq C/P \leq 254$

AUTO_PDC_EN Automatic Programmed Delay Control, Address 0x27[6]

Enabling the AUTO_PDC_EN function activates a function within the ADV7189B that automatically programs the LTA[1:0] and CTA[2:0] to have the chroma and luma data match delays for all modes of operation. If set, manual registers LTA[1:0] and CTA[2:0] are not used by the ADV7189B. If the automatic mode is disabled (via setting the AUTO_PDC_EN bit to 0), the values programmed into the LTA[1:0] and CTA[2:0] registers become active.

When AUTO_PDC_EN is 0, the ADV7189B uses the LTA[1:0] and CTA[2:0] values for delaying luma and chroma samples. Refer to the LTA[1:0] Luma Timing Adjust, Address 0x27[1:0] and the CTA[2:0] Chroma Timing Adjust, Address 0x27[5:3] sections.

When AUTO_PDC_EN is 1 (default), the ADV7189B automatically determines the LTA and CTA values to have luma and chroma aligned at the output.

LTA[1:0] Luma Timing Adjust, Address 0x27[1:0]

The Luma Timing Adjust register allows the user to specify a timing difference between chroma and luma samples.

Note there is a certain functionality overlap with the CTA[2:0] register. For manual programming, use the following defaults:

- CVBS input LTA[1:0] = 00
- YC input LTA[1:0] = 01
- YPrPb input LTA[1:0] = 01

Table 53. LTA Function

LTA[1:0]	Description
00 (default)	No delay.
01	Luma 1 CLK (37 ns) delayed.
10	Luma 2 CLK (74 ns) early.
11	Luma 1 CLK (37 ns) early.

CTA[2:0] Chroma Timing Adjust, Address 0x27[5:3]

The Chroma timing adjust register allows the user to specify a timing difference between chroma and luma samples. This can be used to compensate for external filter group delay differences in the luma vs. chroma path, and to allow a different number of pipeline delays while processing the video downstream. Review this functionality together with the LTA[1:0] register.

The chroma can be delayed/advanced only in chroma pixel steps. One chroma pixel step is equal to two luma pixels. The programmable delay occurs after demodulation, where one can no longer delay by luma pixel steps.

For manual programming, use the following defaults:

- CVBS input CTA[2:0] = 011.
- YC input CTA[2:0] = 101.
- YPrPb input CTA[2:0] = 110.

Table 54. CTA Function

CTA[2:0]	Description
000	Not used.
001	Chroma + 2 chroma pixel (early).
010	Chroma + 1 chroma pixel (early).
011 (default)	No delay.
100	Chroma – 1 chroma pixel (late).
101	Chroma – 2 chroma pixel (late).
110	Chroma – 3 chroma pixel (late).
111	Not used.

SYNCHRONIZATION OUTPUT SIGNALS

HS Configuration

The following controls allow the user to configure the behavior of the HS output pin only:

- Beginning of HS signal via HSB[10:0]
- End of HS signal via HSE[10:0]
- Polarity of HS using PHS

The HS Begin and HS End registers allow the user to freely position the HS output (pin) within the video line. The values in HSB[10:0] and HSE[10:0] are measured in pixel units from the falling edge of HS. Using both values, the user can program both the position and length of the HS output signal.

HSB[10:0] HS Begin, Address 0x34[6:4], Address 0x35[7:0]

The position of this edge is controlled by placing a binary number into HSB[10:0]. The number applied offsets the edge with respect to an internal counter that is reset to 0 immediately after EAV code FF, 00, 00, XY (see Figure 20). HSB is set to 00000000010b, which is 2 LLC1 clock cycles from count[0].

The default value of HSB is 0x002, indicating that the HS pulse starts two pixels after the falling edge of HS.

HSE[10:0] HS End, Address 0x34[2:0], Address 0x36[7:0]

The position of this edge is controlled by placing a binary number into HSE[10:0]. The number applied offsets the edge with respect to an internal counter that is reset to 0 immediately after EAV Code FF, 00, 00, XY (see Figure 20). HSE is set to 00000000000b, which is 0 LLC1 clock cycles from count[0].

The default value of HSE[10:0] is 000, indicating that the HS pulse ends zero pixels after falling edge of HS.

For example:

1. To shift the HS toward active video by 20 LLC1s, add 20 LLC1s to both HSB and HSE, that is, HSB[10:0] = [00000010110], HSE[10:0] = [00000010100].
2. To shift the HS away from active video by 20 LLC1s, add 1696 LLC1s to both HSB and HSE (for NTSC), that is, HSB[10:0] = [1101010010], HSE[10:0] = [11010100000] (1696 is derived from the NTSC total number of pixels = 1716).

To move 20 LLC1s away from active video is equal to subtracting 20 from 1716 and adding the result in binary to both HSB[10:0] and HSE[10:0].

PHS Polarity HS, Address 0x37[7]

The polarity of the HS pin can be inverted using the PHS bit.

When PHS is 0 (default), HS is active high.

When PHS is 1, HS is active low.

Table 55. HS Timing Parameters (See Figure 20)

Standard	Characteristic				
	HS Begin Adjust (HSB[10:0]) (Default)	HS End Adjust (HSE[10:0]) (Default)	HS to Active Video (LLC1 Clock Cycles) (C in Figure 20) (Default)	Active Video Samples/Line (D in Figure 20)	Total LLC1 Clock Cycles (E in Figure 20)
NTSC	00000000010b	00000000000b	272	$720Y + 720C = 1440$	1716
NTSC Square Pixel	00000000010b	00000000000b	276	$640Y + 640C = 1280$	1560
PAL	00000000010b	00000000000b	284	$720Y + 720C = 1440$	1728

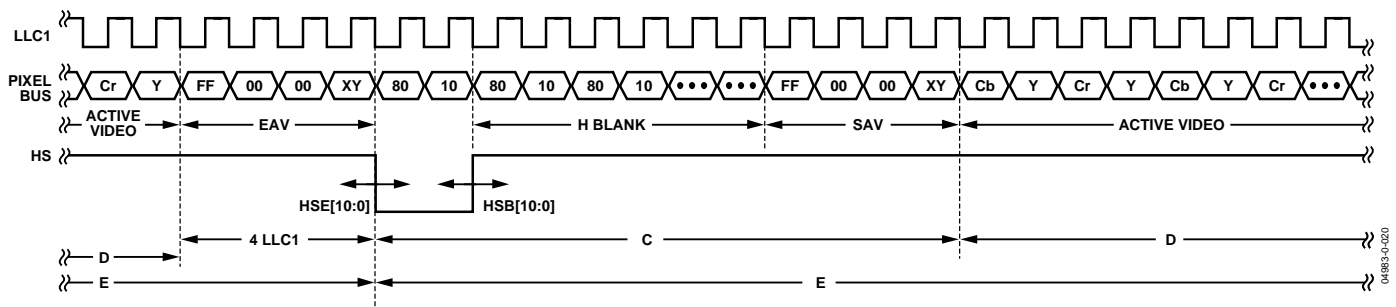

Figure 20. HS Timing

VS and FIELD Configuration

The following controls allow the user to configure the behavior of the VS and FIELD output pins, as well as to generate embedded AV codes:

- ADV encoder-compatible signals via NEWAVMODE
- PVS, PF
- HVSTIM
- VSBHO, VSBHE
- VSEHO, VSEHE
- For NTSC control:
 - NVBEGDELO, NVBEGDELE, NVBEGSIGN, NVBEG[4:0]
 - NVENDDELO, NVENDDELE, NVENDSIGN, NVEND[4:0]
 - NFTOGDELO, NFTOGDELE, NFTOGSIGN, NFTOG[4:0]
- For PAL control:
 - PVBEGDELO, PVBEGDELE, PVBEGSIGN, PVBEG[4:0]
 - PVENDDELO, PVENDDELE, PVENDSIGN, PVEND[4:0]
 - PFTOGDELO, PFTOGDELE, PFTOGSIGN, PFTOG[4:0]

NEWAVMODE New AV Mode, Address 0x31[4]

When NEWAVMODE is 0, EAV/SAV codes are generated to suit ADI encoders. No adjustments are possible.

Setting NEWAVMODE to 1 (default) enables the manual position of the VSYNC, Field, and AV codes using Registers 0x34 to 0x37 and Register 0xE5 to 0xEA. Default register settings are CCIR656 compliant; see Figure 21 for NTSC and Figure 26 for PAL. For recommended manual user settings, see Table 56 and Figure 22 for NTSC; see Table 57 and Figure 27 for PAL.

HVSTIM Horizontal VS Timing, Address 0x31[3]

The HVSTIM bit allows the user to select where the VS signal is being asserted within a line of video. Some interface circuitry can require VS to go low while HS is low.

When HVSTIM is 0 (default) the start of the line is relative to HSE.

When HVSTIM is 1, the start of the line is relative to HSB.

VSBHO VS Begin Horizontal Position Odd, Address 0x32[7]

The VSBHO and VSBHE bits select the position within a line at which the VS pin (not the bit in the AV code) becomes active. Some follow-on chips require the VS pin to change state only when HS is high/low.

When VSBHO is 0 (default), the VS pin goes high at the middle of a line of video (odd field).

When VSBHO is 1, the VS pin changes state at the start of a line (odd field).

VSBHE VS Begin Horizontal Position Even, Address 0x32[6]

The VSBHO and VSBHE bits select the position within a line at which the VS pin (not the bit in the AV code) becomes active. Some follow-on chips require the VS pin to change state only when HS is high/low.

When VSBHE is 0 (default), the VS pin goes high at the middle of a line of video (even field).

When VSBHE is 1, the VS pin changes state at the start of a line (even field).

VSEHO VS End Horizontal Position Odd, Address 0x33[7]

The VSEHO and VSEHE bits select the position within a line at which the VS pin (not the bit in the AV code) becomes active. Some follow-on chips require the VS pin to change state only when HS is high/low.

When VSEHO is 0, the VS pin goes low (inactive) at the middle of a line of video (odd field).

When VSEHO is 1 (default), the VS pin changes state at the start of a line (odd field).

VSEHE VS End Horizontal Position Even, Address 0x33[6]

The VSEHO and VSEHE bits select the position within a line at which the VS pin (not the bit in the AV code) becomes active. Some follow-on chips require the VS pin to change state only when HS is high/low.

When VSEHE is 0 (default), the VS pin goes low (inactive) at the middle of a line of video (even field).

When VSEHE is 1, the VS pin changes state at the start of a line (even field).

PVS Polarity VS, Address 0x37[5]

The polarity of the VS pin can be inverted using the PVS bit. When PVS is 0 (default), VS is active high. When PVS is 1, VS is active low.

PF Polarity FIELD, Address 0x37[3]

The polarity of the FIELD pin can be inverted using the PF bit. When PF is 0 (default), FIELD is active high. When PF is 1, FIELD is active low.

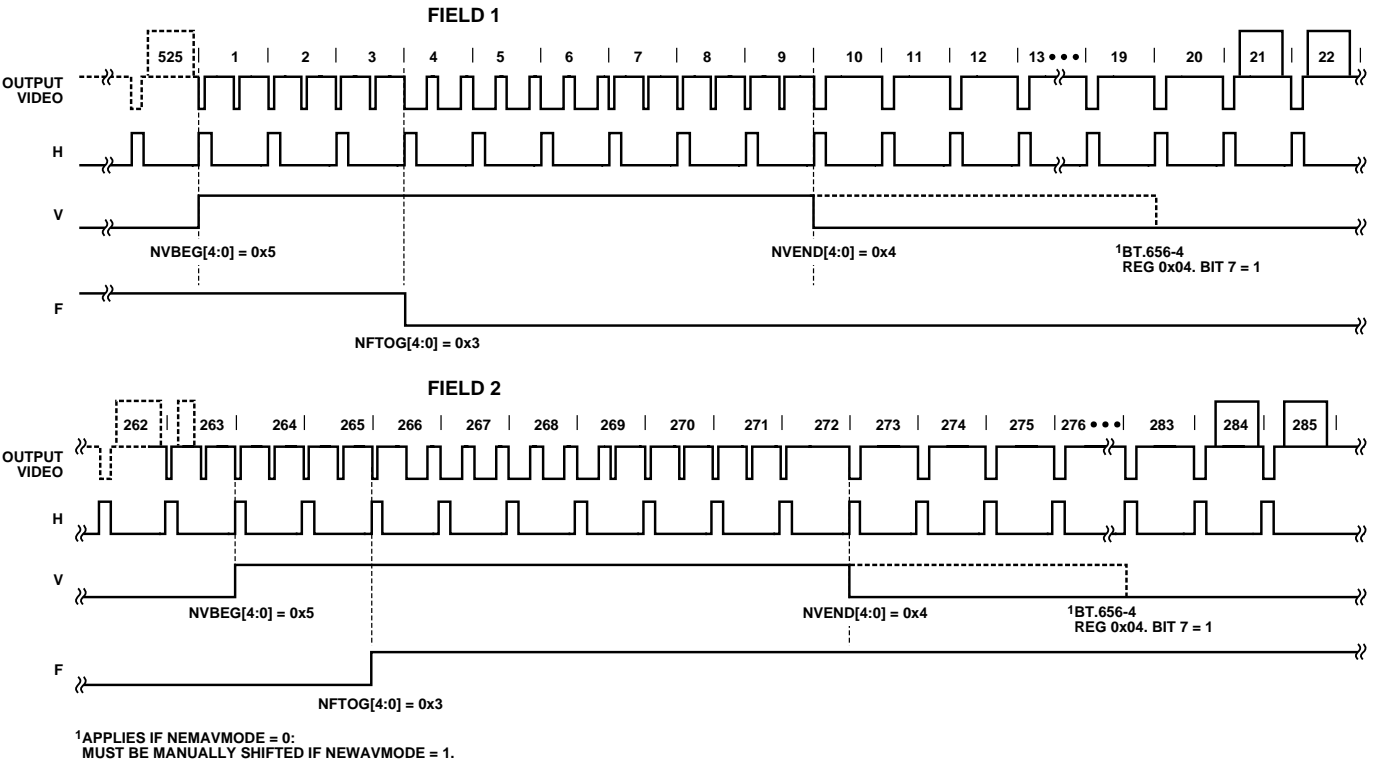

Figure 21. NTSC Default (BT.656). The polarity of H, V, and F is embedded in the data.

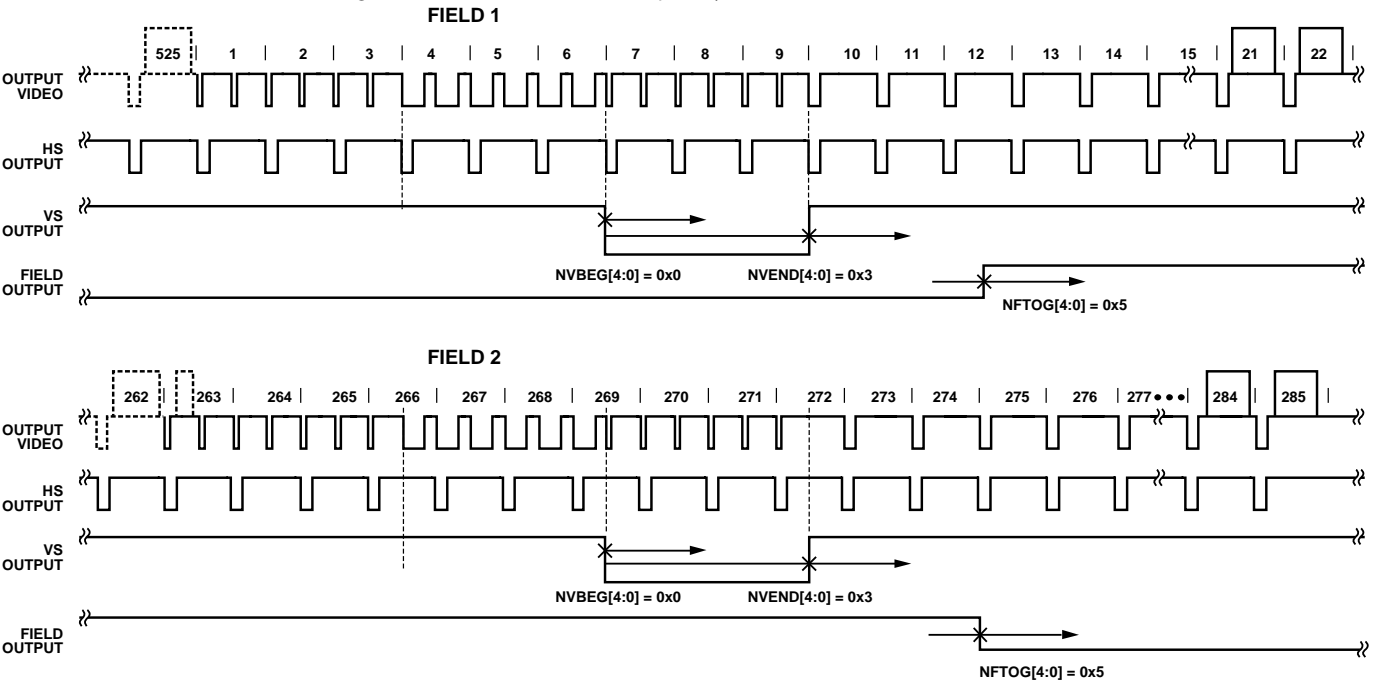

Figure 22. NTSC Typical Vsync/Field Positions Using Register Writes Shown in Table 56

Table 56. Recommended User Settings for NTSC (See Figure 22)

Register	Register Name	Write
0x31	Vsync Field Control 1	0x1A
0x32	Vsync Field Control 2	0x81
0x33	Vsync Field Control 3	0x84
0x34	Hsync Position Control 1	0x00
0x35	Hsync Position Control 2	0x00
0x36	Hsync Position Control 3	0x7D
0x37	Polarity	0xA1
0xE5	NTSV_V_Bit_Beg	0x41
0xE6	NTSC_V_Bit_End	0x84
0xE7	NTSC_F_Bit_Tog	0x06

Figure 23. NTSC Vsync Begin

NVBEGDELO NTSC Vsync Begin Delay on Odd Field, Address 0xE5[7]

When NVBEGDELO is 0 (default), there is no delay.

Setting NVBEGDELO to 1 delays Vsync going high on an odd field by a line relative to NVBEG.

NVBEGDELE NTSC Vsync Begin Delay on Even Field, Address 0xE5[6]

When NVBEGDELE is 0 (default), there is no delay.

Setting NVBEGDELE to 1 delays Vsync going high on an even field by a line relative to NVBEG.

NVBEGSIGN NTSC Vsync Begin Sign, Address 0xE5[5]

Setting NVBEGSIGN to 0 delays the start of Vsync. Set for user manual programming.

Setting NVBEGSIGN to 1 (default), advances the start of Vsync. Not recommended for user programming.

NVBEG[4:0] NTSC Vsync Begin, Address 0xE5[4:0]

The default value of NVBEG is 00101, indicating the NTSC Vsync begin position.

For all NTSC/PAL Vsync timing controls, both the V bit in the AV code and the Vsync on the VS pin are modified.

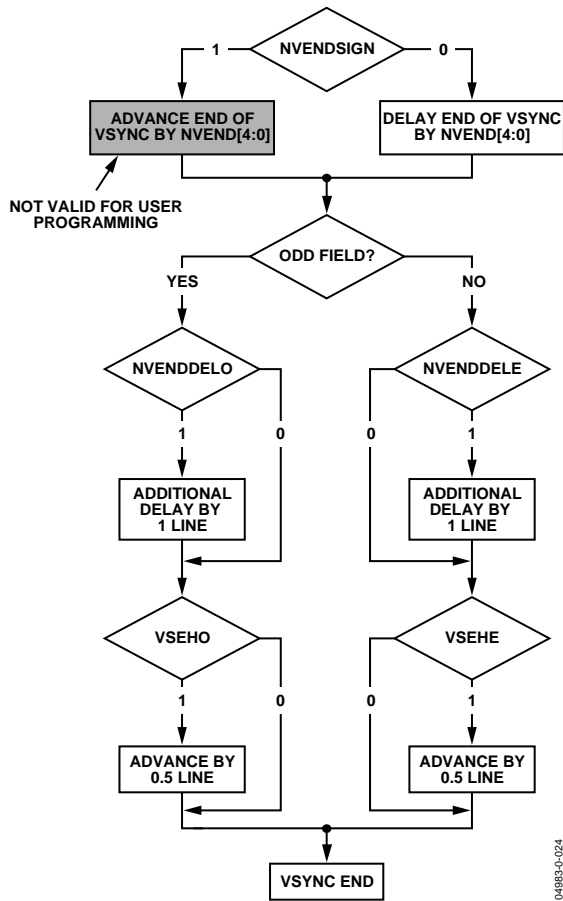

Figure 24. NTSC Vsync End

NVENDDELO NTSC Vsync End Delay on Odd Field, Address 0xE6[7]

When NVENDDELO is 0 (default), there is no delay.

Setting NVENDDELO to 1 delays Vsync from going low on an odd field by a line relative to NVEND.

NVENDDELE NTSC Vsync End Delay on Even Field, Address 0xE6[6]

When NVENDDELE is set to 0 (default), there is no delay.

Setting NVENDDELE to 1 delays Vsync from going low on an even field by a line relative to NVEND.

NVENDSIGN NTSC Vsync End Sign, Address 0xE6[5]

Setting NVENDSIGN to 0 (default) delays the end of Vsync. Set for user manual programming.

Setting NVENDSIGN to 1 advances the end of Vsync. Not recommended for user programming.

NVEND NTSC[4:0] Vsync End, Address 0xE6[4:0]

The default value of NVEND is 00100, indicating the NTSC Vsync end position.

For all NTSC/PAL Vsync timing controls, both the V bit in the AV code and the Vsync on the VS pin are modified.

NFTOGDELO NTSC Field Toggle Delay on Odd Field, Address 0xE7[7]

When NFTOGDELO is 0 (default), there is no delay.

Setting NFTOGDELO to 1 delays the field toggle/transition on an odd field by a line relative to NFTOG.

NFTOGDELE NTSC Field Toggle Delay on Even Field, Address 0xE7[6]

When NFTOGDELE is 0 (default), there is no delay.

Setting NFTOGDELE to 1 delays the field toggle/transition on an even field by a line relative to NFTOG.

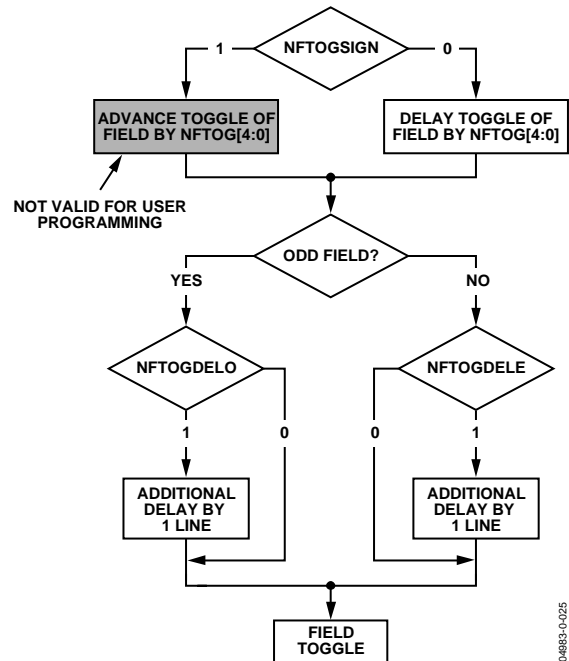

Figure 25. NTSC FIELD Toggle

NFTOGSIGN NTSC Field Toggle Sign, Address 0xE7[5]

Setting NFTOGSIGN to 0 delays the field transition. Set for user manual programming.

Setting NFTOGSIGN to 1 (default) advances the field transition. Not recommended for user programming.

NFTOG[4:0] NTSC Field Toggle, Address 0xE7[4:0]

The default value of NFTOG is 00011, indicating the NTSC Field toggle position.

For all NTSC/PAL FIELD timing controls, both the F bit in the AV code and the FIELD signal on the FIELD pin are modified.

Table 57. Recommended User Settings for PAL (See Figure 27)

Register	Register Name	Write
0x31	Vsync Field Control 1	0x1A
0x32	Vsync Field Control 2	0x81
0x33	Vsync Field Control 3	0x84
0x34	Hsync Position. Control 1	0x00
0x35	Hsync Position. Control 2	0x00
0x36	Hsync Position. Control 3	0x7D
0x37	Polarity	0x29
0xE8	PAL_V_Bit_Beg	0x41
0xE9	PAL_V_Bit_End	0x84
0xEA	PAL_F_Bit_Tog	0x06

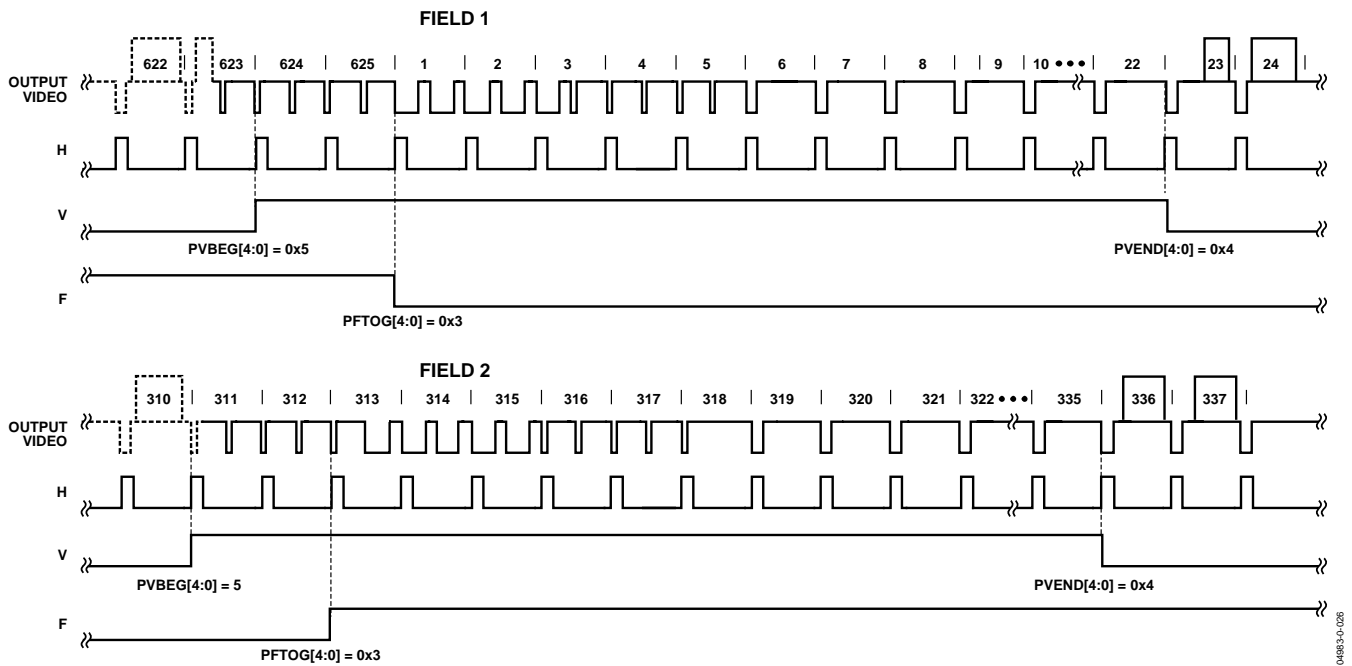

Figure 26. PAL Default (BT.656). The polarity of H, V, and F is embedded in the data.

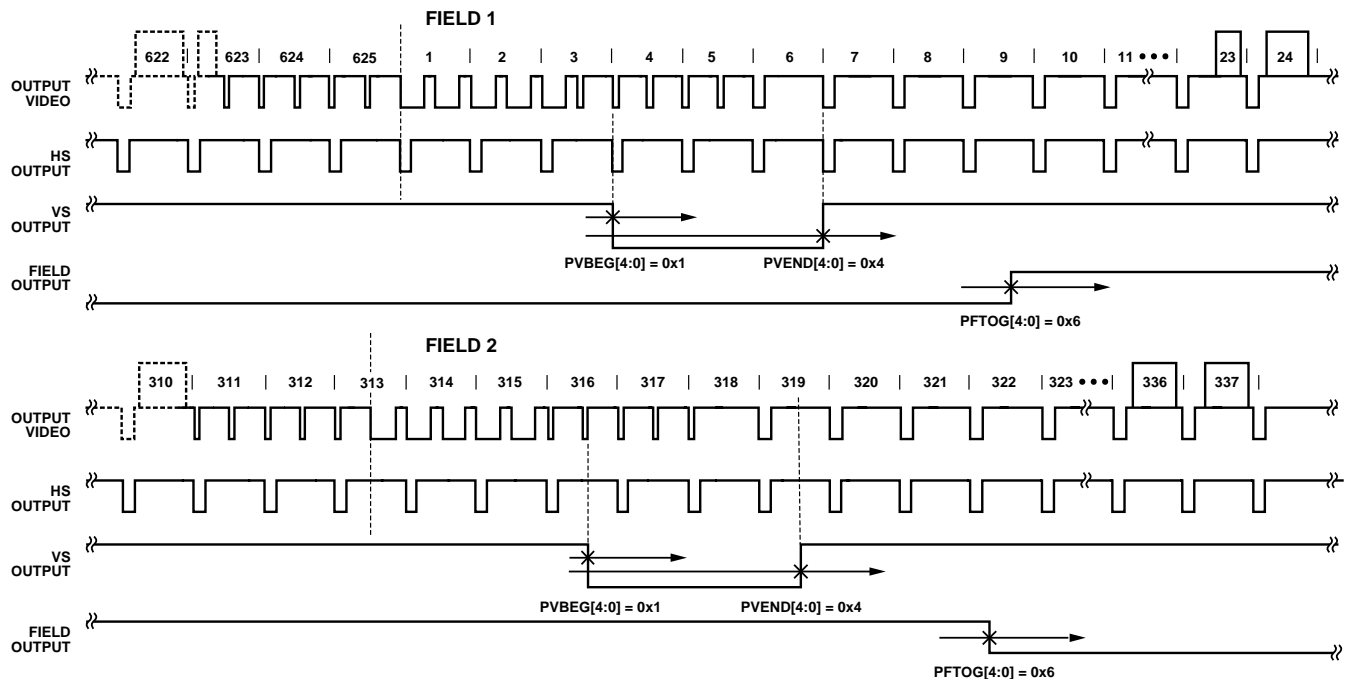

Figure 27. PAL Typical Vsync/Field Positions Using Register Writes in Table 57

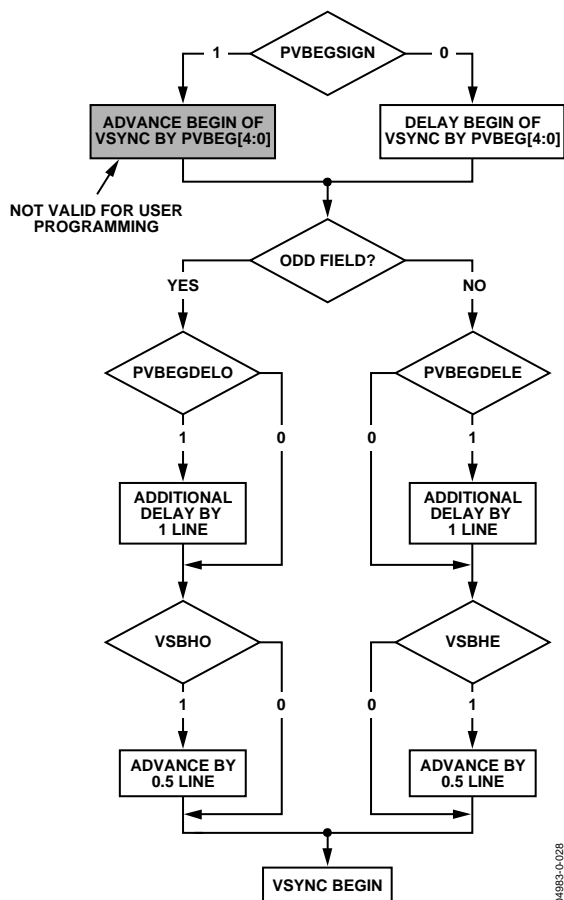

Figure 28. PAL Vsync Begin

PVBEGDELO PAL Vsync Begin Delay on Odd Field, Address 0xE8[7]

When PVBEGDELO is 0 (default), there is no delay.

Setting PVBEGDELO to 1 delays Vsync going high on an odd field by a line relative to PVBEG.

PVBEGDELE PAL Vsync Begin Delay on Even Field, Address 0xE8[6]

When PVBEGDELE is 0, there is no delay.

Setting PVBEGDELE to 1 (default) delays Vsync going high on an even field by a line relative to PVBEG.

PVBEGSIGN PAL Vsync Begin Sign, Address 0xE8[5]

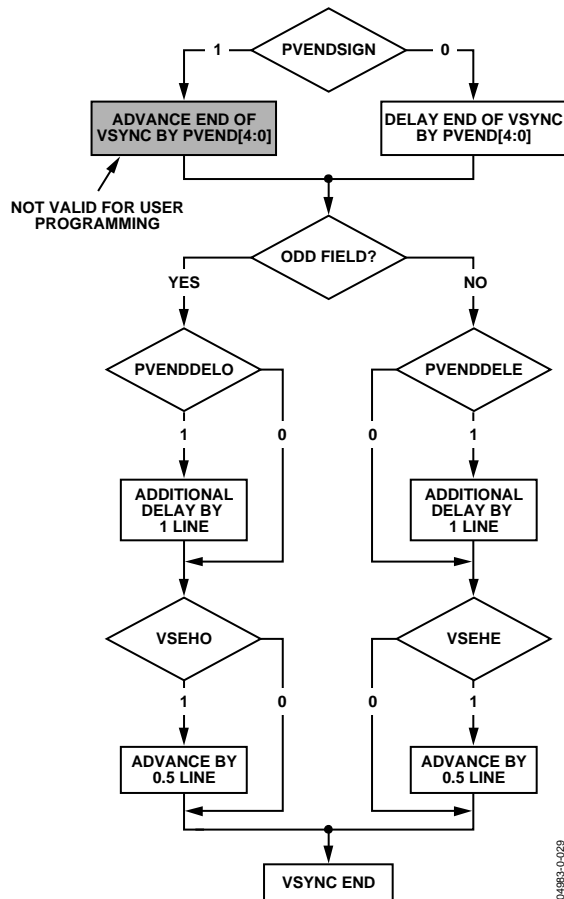

Setting PVBEGSIGN to 0 delays the beginning of Vsync. Set for user manual programming.

Setting PVBEGSIGN to 1 (default) advances the beginning of Vsync. Not recommended for user programming.

PVBEG[4:0] PAL Vsync Begin, Address 0xE8[4:0]

The default value of PVBEG is 00101, indicating the PAL Vsync begin position.

For all NTSC/PAL Vsync timing controls, both the V bit in the AV code and the Vsync on the VS pin are modified.

PVENDDELO PAL Vsync End Delay on Odd Field, Address 0xE9[7]

When PVENDDELO is 0 (default), there is no delay.

Setting PVENDDELO to 1 delays Vsync going low on an odd field by a line relative to PVEND.

PVENDDELE PAL Vsync End Delay on Even Field, Address 0xE9[6]

When PVENDDELE is 0 (default), there is no delay.

Setting PVENDDELE to 1 delays Vsync going low on an even field by a line relative to PVEND.

PVENDSIGN PAL Vsync End Sign, Address 0xE9[5]

Setting PVENDSIGN to 0 (default) delays the end of Vsync. Set for user manual programming.

Setting PVENDSIGN to 1 advances the end of Vsync. Not recommended for user programming.

PVEND[4:0] PAL Vsync End, Address 0xE9[4:0]

The default value of PVEND is 10100, indicating the PAL Vsync end position.

For all NTSC/PAL Vsync timing controls, both the V bit in the AV code and the Vsync on the VS pin are modified.

PFTOGDELO PAL Field Toggle Delay on Odd Field, Address 0xEA[7]

When PFTOGDELO is 0 (default), there is no delay.

Setting PFTOGDELO to 1 delays the F toggle/transition on an odd field by a line relative to PFTOG.

PFTOGDELE PAL Field Toggle Delay on Even Field, Address 0xEA[6]

When PFTOGDELE is 0, there is no delay.

Setting PFTOGDELE to 1 (default) delays the F toggle/transition on an even field by a line relative to PFTOG.

PFTOGSIGN PAL Field Toggle Sign, Address 0xEA[5]

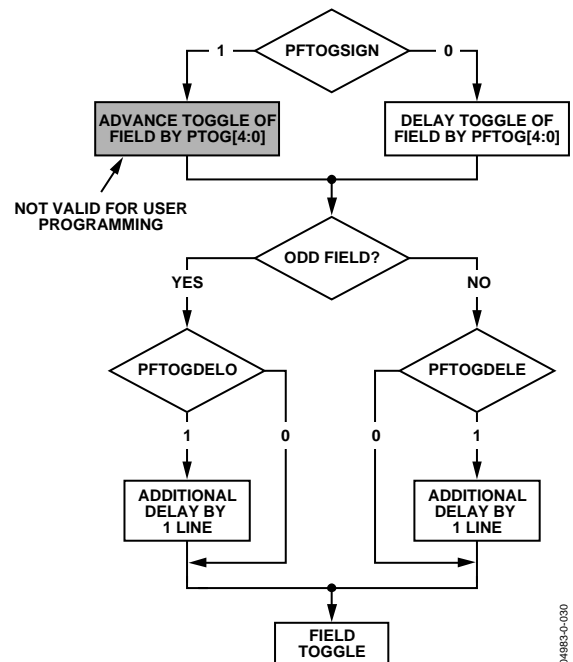

Setting PFTOGSIGN to 0 delays the field transition. Set for user manual programming.

Setting PFTOGSIGN to 1 (default) advances the field transition. Not recommended for user programming.

PFTOG PAL Field Toggle, Address 0xEA[4:0]

The default value of PFTOG is 00011, indicating the PAL field toggle position.

For all NTSC/PAL field timing controls, the F bit in the AV code and the Field signal on the FIELD/DE pin are modified.

SYNC PROCESSING

The ADV7189B has two additional sync processing blocks that postprocess the raw synchronization information extracted from the digitized input video. If desired, the blocks can be disabled via the following two I²C bits.

ENHSPLL Enable Hsync Processor, Address 0x01[6]

The Hsync processor is designed to filter incoming Hsyncs that have been corrupted by noise, providing improved performance for video signals with stable time bases but poor SNR.

Setting ENHSPLL to 0 disables the Hsync processor.

Setting ENHSPLL to 1 (default) enables the Hsync processor.

ENVSPROC Enable Vsync Processor, Address 0x01[3]

This block provides extra filtering of the detected Vsyncs to give improved vertical lock.

Setting ENVSPROC to 0 disables the Vsync processor.

Setting ENVSPROC to 1 (default) enables the Vsync processor.

VBI DATA DECODE

The following low data rate VBI signals can be decoded by the ADV7189B:

- Wide screen signaling (WSS)
- Copy generation management systems (CGMS)
- Closed captioning (CC)
- EDTV
- Gemstar 1× and 2× compatible data recovery

The presence of any of the above signals is detected and, if applicable, a parity check is performed. The result of this testing is contained in a confidence bit in the VBI Info[7:0] register. Users are encouraged to first examine the VBI Info register before reading the corresponding data registers. All VBI data decode bits are read-only.

All VBI data registers are double-buffered with the field signals. This means that data is extracted from the video lines and appears in the appropriate I²C registers with the next field transition. They are then static until the next field.

The user should start an I²C read sequence with VS by first examining the VBI Info register. Then, depending on what data was detected, the appropriate data registers should be read.

The data registers are filled with decoded VBI data even if their corresponding detection bits are low; it is likely that bits within the decoded data stream are wrong.

The closed captioning data (CCAP) is available in the I²C registers, and is also inserted into the output video data stream during horizontal blanking.

The Gemstar-compatible data is not available in the I²C registers, and is inserted into the data stream only during horizontal blanking.

WSSD Wide Screen Signaling Detected, Address 0x90[0]

Logic 1 for this bit indicates the data in the WSS1 and WSS2 registers is valid.

The WSSD bit goes high if the rising edge of the start bit is detected within a time window, and if the polarity of the parity bit matches the transmitted data.

When WSSD is 0, no WSS is detected and confidence in the decoded data is low.

When WSSD is 1, WSS is detected and confidence in the decoded data is high.

CCAPD Closed Caption Detected, Address 0x90[1]

Logic 1 for this bit indicates the data in the CCAP1 and CCAP2 registers is valid.

The CCAPD bit goes high if the rising edge of the start bit is detected within a time window, and if the polarity of the parity bit matches the transmitted data.

When CCAPD is 0, no CCAP signals are detected and confidence in the decoded data is low.

When CCAPD is 1, the CCAP sequence is detected and confidence in the decoded data is high.

EDTVD EDTV Sequence Detected, Address 0x90[2]

Logic 1 for this bit indicates the data in the EDTV1, 2, 3 registers is valid.

The EDTVD bit goes high if the rising edge of the start bit is detected within a time window, and if the polarity of the parity bit matches the transmitted data.

When EDTVD is 0, no EDTV sequence is detected. Confidence in decoded data is low.

When EDTVD is 1, an EDTV sequence is detected. Confidence in decoded data is high.

CGMSD CGMS-A Sequence Detected, Address 0x90[3]

Logic 1 for this bit indicates the data in the CGMS1, 2, 3 registers is valid. The CGMSD bit goes high if a valid CRC checksum has been calculated from a received CGMS packet.

When CGMSD is 0, no CGMS transmission is detected and confidence in the decoded data is low.

When CGMSD is 1, the CGMS sequence is decoded and confidence in the decoded data is high.

CRC_ENABLE CRC CGMS-A Sequence, Address 0xB2[2]

For certain video sources, the CRC data bits can have an invalid format. In such circumstances, the CRC checksum validation procedure can be disabled. The CGMSD bit goes high if the rising edge of the start bit is detected within a time window.

When CRC_ENABLE is 0, no CRC check is performed. The CGMSD bit goes high if the rising edge of the start bit is detected within a time window.

When CRC_ENABLE is 1 (default), CRC checksum is used to validate the CGMS sequence. The CGMSD bit goes high for a valid checksum. ADI recommended setting.

Wide Screen Signaling Data

WSS1[7:0], Address 0x91[7:0], WSS2[7:0], Address 0x92[7:0]

Figure 31 shows the bit correspondence between the analog video waveform and the WSS1/WSS2 registers. WSS2[7:6] are undetermined and should be masked out by software.

EDTV Data Registers

EDTV1[7:0], Address 0x93[7:0],

EDTV2[7:0], Address 0x94[7:0],

EDTV3[7:0], Address 0x95[7:0]

Figure 32 shows the bit correspondence between the analog video waveform and the EDTV1/EDTV2/EDTV3 registers.

EDTV3[7:6] are undetermined and should be masked out by software. EDTV3[5] is reserved for future use and, for now, contains a 0. The three LSBs of the EDTV waveform are currently not supported.

Figure 31. WSS Data Extraction

04983-0-031

Table 58. WSS Access Information

Signal Name	Register Location	Address		Register Default Value
WSS1[7:0]	WSS 1[7:0]	145d	0x91	Readback Only
WSS2[5:0]	WSS 2[5:0]	146d	0x92	Readback Only

Figure 32. EDTV Data Extraction

04983-0-032

Table 59. EDTV Access Information

Signal Name	Register Location	Address		Register Default Value
EDTV1[7:0]	EDTV 1[7:0]	147d	0x93	Readback Only
EDTV2[7:0]	EDTV 2[7:0]	148d	0x94	Readback Only
EDTV3[7:0]	EDTV 3[7:0]	149d	0x95	Readback Only

CGMS Data Registers

CGMS1[7:0], Address 0x96[7:0],
CGMS2[7:0], Address 0x97[7:0],
CGMS3[7:0], Address 0x98[7:0]

Figure 33 shows the bit correspondence between the analog video waveform and the CGMS1/CGMS2/CGMS3 registers. CGMS3[7:4] are undetermined and should be masked out by software.

Closed Caption Data Registers

CCAP1[7:0], Address 0x99[7:0],
CCAP2[7:0], Address 0x9A[7:0]

Figure 34 shows the bit correspondence between the analog video waveform and the CCAP1/CCAP2 registers. CCAP1[7] contains the parity bit from the first word. CCAP2[7] contains the parity bit from the second word. Refer to the GDECAD Gemstar Decode Ancillary Data Format, Address 0x4C[0] section.

Figure 33. CGMS Data Extraction

Table 60. CGMS Access Information

Signal Name	Register Location	Address		Register Default Value
CGMS1[7:0]	CGMS 1[7:0]	150d	0x96	Readback Only
CGMS2[7:0]	CGMS 2[7:0]	151d	0x97	Readback Only
CGMS3[3:0]	CGMS 3[3:0]	152d	0x98	Readback Only

Figure 34. Closed-Caption Data Extraction

Table 61. CCAP Access Information

Signal Name	Register Location	Address		Register Default Value
CCAP1[7:0]	CCAP 1[7:0]	153d	0x99	Readback Only
CCAP2[7:0]	CCAP 2[7:0]	154d	0x9A	Readback Only

Letterbox Detection

Incoming video signals may conform to different aspect ratios (16:9 wide screen of 4:3 standard). For certain transmissions in the wide screen format, a digital sequence (WSS) is transmitted with the video signal. If a WSS sequence is provided, the aspect ratio of the video can be derived from the digitally decoded bits WSS contains.

In the absence of a WSS sequence, letterbox detection can be used to find wide screen signals. The detection algorithm examines the active video content of lines at the start and end of a field. If black lines are detected, this may indicate the currently shown picture is in wide screen format.

The active video content (luminance magnitude) over a line of video is summed together. At the end of a line, this accumulated value is compared with a threshold, and a decision is made as to whether or not a particular line is black. The threshold value needed may depend on the type of input signal; some control is provided via LB_TH[4:0].

Detection at the Start of a Field

The ADV7189B expects a section of at least six consecutive black lines of video at the top of a field. Once those lines are detected, Register LB_LCT[7:0] reports back the number of black lines that were actually found. By default, the ADV7189B starts looking for those black lines in sync with the beginning of active video, for example, straight after the last VBI video line. LB_SL[3:0] allows the user to set the start of letterbox detection from the beginning of a frame on a line-by-line basis. The detection window closes in the middle of the field.

Detection at the End of a Field

The ADV7189B expects at least six continuous lines of black video at the bottom of a field before reporting back the number of lines actually found via the LB_LCB[7:0] value. The activity window for letterbox detection (end of field) starts in the middle of an active field. Its end is programmable via LB_EL[3:0].

Detection at the Midrange

Some transmissions of wide screen video include subtitles within the lower black box. If the ADV7189B finds at least two black lines followed by more nonblack video, for example, the subtitle, and is then followed by the remainder of the bottom black block, it reports back a midcount via LB_LCM[7:0]. If no subtitles are found, LB_LCM[7:0] reports the same number as LB_LCB[7:0].

There is a 2-field delay in the reporting of any line count parameters.

There is no letterbox detected bit. The user is asked to read the LB_LCT[7:0] and LB_LCB[7:0] register values and to conclude whether or not the letterbox-type video is present in software.

LB_LCT[7:0] Letterbox Line Count Top, Address 0x9B[7:0]; LB_LCM[7:0] Letterbox Line Count Mid, Address 0x9C[7:0]; LB_LCB[7:0] Letterbox Line Count Bottom, Address 0x9D[7:0]

Table 62. LB_LCx Access Information

Signal Name	Address	Register Default Value
LB_LCT[7:0]	0x9B	Readback only
LB_LCM[7:0]	0x9C	Readback only
LB_LCB[7:0]	0x9D	Readback only

LB_TH[4:0] Letterbox Threshold Control, Address 0xDC[4:0]

Table 63. LB_TH Function

LB_TH[4:0]	Description
01100 (default)	Default threshold for detection of black lines.
01101 to 10000	Increase threshold (need larger active video content before identifying nonblack lines).
00000 to 01011	Decrease threshold (even small noise levels can cause the detection of nonblack lines).

LB_SL[3:0] Letterbox Start Line, Address 0xDD[7:4]

The LB_SL[3:0] bits are set at 0100b by default. This means the letterbox detection window starts after the EDTV VBI data line. For an NTSC signal this window is from Line 23 to Line 286.

Changing the bits to 0101, the detection window starts on Line 24 and ends on Line 287.

LB_EL[3:0] Letterbox End Line, Address 0xDD[3:0]

The LB_EL[3:0] bits are set at 1101b by default. This means the letterbox detection window ends with the last active video line. For an NTSC signal, this window is from Line 262 to Line 525.

Changing the bits to 1100, the detection window starts on Line 261 and ends on Line 254.

Gemstar Data Recovery

The Gemstar-compatible data recovery block (GSCD) supports 1× and 2× data transmissions. In addition, it can serve as a closed-caption decoder. Gemstar-compatible data transmissions can occur only in NTSC. Closed-caption data can be decoded in both PAL and NTSC.

The block is configured via I²C in the following ways:

- GDECEL[15:0] allow data recovery on selected video lines on even fields to be enabled and disabled.
- GDECOL[15:0] enable the data recovery on selected lines for odd fields.
- GDECAD configures the way in which data is embedded in the video data stream.

The recovered data is not available through I²C, but is being inserted into the horizontal blanking period of an ITU-R. BT656-compatible data stream. The data format is intended to comply with the recommendation by the International Telecommunications Union, ITU-R BT.1364. See Figure 35. For more information, see the ITU website at www.itu.ch.

The format of the data packet depends on the following criteria:

- Transmission is 1× or 2×.
- Data is output in 8-bit or 4-bit format (see the description of the GDECAD Gemstar Decode Ancillary Data Format, Address 0x4C[0] bit).
- Data is closed caption (CCAP) or Gemstar compatible.

Data packets are output if the corresponding enable bit is set (see the GDECEL and GDECOL descriptions), and if the decoder detects the presence of data. This means for video lines where no data has been decoded, no data packet is output even if the corresponding line enable bit is set.

Each data packet starts immediately after the EAV code of the preceding line.

Figure 35 and Table 64 show the overall structure of the data packet.

Entries within the packet are as follows:

- Fixed preamble sequence of 0x00, 0xFF, 0xFF.
- Data identification word (DID). The value for the DID marking a Gemstar or CCAP data packet is 0x140 (10-bit value).
- Secondary data identification word (SDID), which contains information about the video line from which data was retrieved, whether the Gemstar transmission was of 1× or 2× format, and whether it was retrieved from an even or odd field.
- Data count byte, giving the number of user data-words that follow.
- User data section.
- Optional padding to ensure that the length of the user data-word section of a packet is a multiple of four bytes (requirement as set in ITU-R BT.1364).
- Checksum byte.

Table 64 lists the values within a generic data packet that is output by the ADV7189B in 10-bit format.

Figure 35. Gemstar and CCAP Embedded Data Packet (Generic)

Table 64. Generic Data Output Packet

Byte	D[9]	D[8]	D[7]	D[6]	D[5]	D[4]	D[3]	D[2]	D[1]	D[0]	Description
0	0	0	0	0	0	0	0	0	0	0	Fixed preamble

Table 65. Data Byte Allocation

2×	Raw Information Bytes Retrieved from the Video Line	GDECAD	User Data-Words (Including Padding)	Padding Bytes	DC[1:0]
1	4	0	8	0	10
1	4	1	4	0	01
0	2	0	4	0	01
0	2	1	4	2	01

Gemstar Bit Names

- DID. The data identification value is 0x140 (10-bit value). Care has been taken that in 8-bit systems, the 2 LSBs do not carry vital information.
- EP and !EP. The EP bit is set to ensure even parity on the data-word D[8:0]. Even parity means there is always an even number of 1s within the D[8:0] bit arrangement. This includes the EP bit. !EP describes the logic inverse of EP and is output on D[9]. The !EP is output to ensure that the reserved codes of 00 and FF cannot happen.
- EF. Even field identifier. EF = 1 indicates that the data was recovered from a video line on an even field.
- 2×. This bit indicates whether the data sliced was in Gemstar 1× or 2× format. A high indicates 2× format.
- Line[3:0]. This entry provides a unique code for each of the possible 16 source lines of video from which Gemstar data may have been retrieved. See Table 74 and Table 75.
- DC[1:0]. Data count value. The number of user data-words in the packet divided by 4. The number of user data-words (UDW) in any packet must be an integral number of 4. Padding is required at the end if necessary (requirement as set in ITU-R BT.1364). See Table 65.
- The 2× bit determines whether the raw information retrieved from the video line was 2 or 4 bytes. The state of the GDECAD bit affects whether the bytes are transmitted straight (that is, two bytes transmitted as two bytes) or whether they are split into nibbles (that is, two bytes transmitted as four half bytes). Padding bytes are then added where necessary.

- CS[8:2]. The checksum is provided to determine the integrity of the ancillary data packet. It is calculated by summing up D[8:2] of DID, SDID, the Data Count byte, and all UDWs, and ignoring any overflow during the summation. Since all data bytes that are used to calculate the checksum have their 2 LSBs set to 0, the CS[1:0] bits are also always 0.

!CS[8] describes the logic inversion of CS[8]. The value !CS[8] is included in the checksum entry of the data packet to ensure that the reserved values of 0x00 and 0xFF do not occur.

Table 66 to Table 69 outline the possible data packages.

Gemstar 2× Format, Half-Byte Output

Half-byte output mode is selected by setting CDECAD = 0; full-byte output mode is selected by setting CDECAD = 1. See the GDECAD Gemstar Decode Ancillary Data Format, Address 0x4C[0] section.

Gemstar 1× Format

Half-byte output mode is selected by setting CDECAD = 0; full-byte output mode is selected by setting CDECAD = 1. See the GDECAD Gemstar Decode Ancillary Data Format, Address 0x4C[0] section.

NTSC CCAP Data

Half-byte output mode is selected by setting CDECAD = 0; the full-byte mode is enabled by CDECAD = 1. See the GDECAD Gemstar Decode Ancillary Data Format, Address 0x4C[0] section. The data packet formats are shown in Table 70 and Table 71.

NTSC closed-caption data is sliced on line 21d on even and odd fields. The corresponding enable bit has to be set high. See the section and the GDECOL[15:0] Gemstar Decoding Odd Lines, Address 0x4A[7:0]; Address 0x4B[7:0] section.

PAL CCAP Data

Half-byte output mode is selected by setting CDECAD = 0; full-byte output mode is selected by setting CDECAD = 1. See the GDECAD Gemstar Decode Ancillary Data Format, Address 0x4C[0] section. Table 72 and Table 73 list the bytes of the data packet.

PAL closed-caption data is sliced from Lines 22 and 335. The corresponding enable bits have to be set.

See the GDECEL[15:0] Gemstar Decoding Even Lines, Address 0x48[7:0]; Address 0x49[7:0] section and the GDECOL[15:0] Gemstar Decoding Odd Lines, Address 0x4A[7:0]; Address 0x4B[7:0] section.

**GDECEL[15:0] Gemstar Decoding Even Lines,
Address 0x48[7:0]; Address 0x49[7:0]**

The 16 bits of the GDECEL[15:0] are interpreted as a collection of 16 individual line decode enable signals. Each bit refers to a line of video in an even field. Setting a bit to 1 enables the decoder block to retrieve Gemstar or closed caption-compatible data on that particular line. Setting a bit to 0 prevents the decoder from trying to retrieve data. See Table 74 and Table 75.

To retrieve closed-caption data services on NTSC (Line 284), GDECEL[11] must be set.

To retrieve closed caption data services on PAL (Line 335), GDECEL[14] must be set.

The default value of GDECEL[15:0] is 0x0000. This setting instructs the decoder not to attempt to decode Gemstar or CCAP data from any line in the even field.

**GDECOL[15:0] Gemstar Decoding Odd Lines,
Address 0x4A[7:0]; Address 0x4B[7:0]**

The 16 bits of the GDECOL[15:0] form a collection of 16 individual line decode enable signals. See Table 74 and Table 75. To retrieve closed caption data services on NTSC (Line 21), GDECOL[11] must be set.

To retrieve closed-caption data services on PAL (Line 22), GDECOL[14] must be set.

The default value of GDECOL[15:0] is 0x0000. This setting instructs the decoder not to attempt to decode Gemstar or CCAP data from any line in the odd field.

**GDECAD Gemstar Decode Ancillary Data Format,
Address 0x4C[0]**

The decoded data from Gemstar-compatible transmissions or closed-caption transmission is inserted into the horizontal blanking period of the respective line of video. A potential problem can arise if the retrieved data bytes have the value 0x00 or 0xFF. In an ITU-R BT.656-compatible data stream, these values are reserved and used only to form a fixed preamble.

The GDECAD bit allows the data to be inserted into the horizontal blanking period in two ways:

- Insert all data straight into the data stream, even the reserved values of 0x00 and 0xFF, if they occur. This can violate the output data format specification ITU-R BT.1364.
- Split all data into nibbles and insert the half-bytes over double the number of cycles in a 4-bit format.

When GDECAD is 0 (default), the data is split into half-bytes and inserted.

When GDECAD is 1, the data is output straight in 8-bit format.

Table 74. NTSC Line Enable Bits and Corresponding Line Numbering

Line[3:0]	Line Number (ITU-R BT.470)	Enable Bit	Comment

Figure 36. NTSC IF Compensation Filter Responses

Figure 37. PAL IF Compensation Filter Responses

See Table 86 for programming details.

I²C Interrupt System

The ADV7189B has a comprehensive interrupt register set. This map is located in the Register Access. See Table 85 for details of the interrupt register map. How to access this map is described in Figure 38.

Figure 38. Register Access, Page 1 and Page 2

IF Compensation Filter

IFFILTSEL[2:0] IF Filter Select Address 0xF8[2:0]

The IFFILTSEL[2:0] register allows the user to compensate for SAW filter characteristics on a composite input as would be observed on tuner outputs. Figure 36 and Figure 37 show IF filter compensation for NTSC and PAL.

The options for this feature are as follows:

- Bypass Mode (default)
- NTSC—consists of three filter characteristics
- PAL—consists of three filter characteristics

Interrupt Request Output Operation

When an interrupt event occurs, the interrupt pin $\overline{\text{INTRQ}}$ goes low with a programmable duration given by $\text{INTRQ_DUR_SEL}[1:0]$.

$\text{INTRQ_DURSEL}[1:0]$, Interrupt Duration Select Address 0x40 (Interrupt Space)[7:6]

Table 76. INTRQ_DUR_SEL

$\text{INTRQ_DURSEL}[1:0]$	Description
00 (default)	3 Xtal periods
01	15 Xtal periods
10	63 Xtal periods
11	Active until cleared

When the active-until-Cleared interrupt duration is selected and the event that caused the interrupt is no longer in force, the interrupt persists until it is masked or cleared.

For example, if the ADV7189B loses lock, an interrupt is generated and the INTRQ pin goes low. If the ADV7189B returns to the locked state, INTRQ continues to drive low until the SD_LOCK bit is either masked or cleared.

Interrupt Drive Level

The ADV7189B resets with open drain enabled and all interrupts masked off. Therefore, INTRQ is in a high impedance state after reset. 01 or 10 has to be written to $\text{INTRQ_OP_SEL}[1:0]$ for a logic level to be driven out from the INTRQ pin.

It is also possible to write to a register in the ADV7189B that manually asserts the INTRQ pin. This bit is MPU_STIM_INTRQ .

$\text{INTRQ_OP_SEL}[1:0]$, Interrupt Duration Select Address 0x40 (Interrupt Space)[1:0]

Table 77. INTRQ_OP_SEL

$\text{INTRQ_OP_SEL}[1:0]$	Description
00 (default)	Open drain
01	Drive low when active
10	Drive high when active
11	Reserved

Multiple Interrupt Events

If Interrupt Event 1 occurs and then Interrupt Event 2 occurs before the system controller has cleared or masked Interrupt Event 1, the ADV7189B does not generate a second interrupt signal. The system controller should check all unmasked interrupt status bits since more than one can be active.

Macrovision Interrupt Selection Bits

The user can select between pseudo sync pulse and color stripe detection as follows:

$\text{MV_INTRQ_SEL}[1:0]$, Macrovision Interrupt Selection Bits Address 0x40 (Interrupt Space)[5:4]

Table 78. MV_INTRQ_SEL

$\text{MV_INTRQ_SEL}[1:0]$	Description
00	Reserved
01 (default)	Pseudo sync only
10	Color stripe only
11	Either pseudo sync or color stripe

Additional information relating to the interrupt system is detailed in Table 84.

PIXEL PORT CONFIGURATION

The ADV7189B has a very flexible pixel port that can be configured in a variety of formats to accommodate downstream ICs. Table 79 and Table 80 summarize the various functions that the ADV7189B pins can have in different modes of operation.

The ordering of components, for example, Cr vs. Cb, CHA/B/C, can be changed. Refer to the SWPC Swap Pixel Cr/Cb, Address 0x27[7] section. Table 79 indicates the default positions for the Cr/Cb components.

OF_SEL[3:0] Output Format Selection, Address 0x03[5:2]

The modes in which the ADV7189B pixel port can be configured are under the control of OF_SEL[3:0]. See Table 80 for details.

The default LLC frequency output on the LLC1 pin is approximately 27 MHz. For modes that operate with a nominal data rate of 13.5 MHz (0001, 0010), the clock frequency on the LLC1 pin stays at the higher rate of 27 MHz. For information on outputting the nominal 13.5 MHz clock on the LLC1 pin, see the LLC1 Output Selection, LLC_PAD_SEL[2:0], Address 0x8F[6:4] section.

SWPC Swap Pixel Cr/Cb, Address 0x27[7]

This bit allows Cr and Cb samples to be swapped.

When SWPC is 0 (default), no swapping is allowed.

When SWPC is 1, the Cr and Cb values can be swapped.

LLC1 Output Selection, LLC_PAD_SEL[2:0], Address 0x8F[6:4]

The following I²C write allows the user to select between the LLC1 (nominally at 27 MHz) and LLC2 (nominally at 13.5 MHz).

The LLC2 signal is useful for LLC2-compatible wide bus (16-/20-bit) output modes. See OF_SEL[3:0] for additional information. The LLC2 signal and data on the data bus are synchronized. By default, the rising edge of LLC1/LLC2 is aligned with the Y data; the falling edge occurs when the data bus holds C data. The polarity of the clock, and therefore the Y/C assignments to the clock edges, can be altered by using the Polarity LLC pin.

When LLC_PAD_SEL[2:0] is 000 (default), the output is nominally 27 MHz LLC on the LLC1 pin.

When LLC_PAD_SEL[2:0] is 101, the output is nominally 13.5 MHz LLC on the LLC1 pin.

Table 79. P19 to P0 Output/Input Pin Mapping

Processor, Format, and Mode	Data Port Pins P[19:0]

MPU PORT DESCRIPTION

The ADV7189B supports a 2-wire (I²C-compatible) serial interface. Two inputs, serial data (SDA) and serial clock (SCLK), carry information between the ADV7189B and the system I²C master controller. Each slave device is recognized by a unique address. The ADV7189B's I²C port allows the user to set up and configure the decoder and to read back captured VBI data. The ADV7189B has four possible slave addresses for both read and write operations, depending on the logic level on the ALSB pin. These four unique addresses are shown in Table 81. The ADV7189B's ALSB pin controls Bit 1 of the slave address. By altering the ALSB, it is possible to control two ADV7189Bs in an application without having a conflict with the same slave address. The LSB (Bit 0) sets either a read or write operation. Logic 1 corresponds to a read operation; Logic 0 corresponds to a write operation.

Table 81. I²C Address for ADV7189B

ALSB	R/W	Slave Address
0	0	0x40
0	1	0x41
1	0	0x42
1	1	0x43

To control the device on the bus, a specific protocol must be followed. First, the master initiates a data transfer by establishing a start condition, which is defined by a high-to-low transition on SDA while SCLK remains high. This indicates that an address/data stream follows. All peripherals respond to the start condition and shift the next eight bits (7-bit address + R/W bit). The bits are transferred from MSB down to LSB. The peripheral that recognizes the transmitted address responds by pulling the data line low during the ninth clock pulse; this is known as an acknowledge bit. All other devices withdraw from the bus at this point and maintain an idle condition. The idle condition is where the device monitors the SDA and SCLK lines, waiting for the start condition and the correct transmitted address.

The R/W bit determines the direction of the data. Logic 0 on the LSB of the first byte means the master writes information to the peripheral. Logic 1 on the LSB of the first byte means the master reads information from the peripheral.

The ADV7189B acts as a standard slave device on the bus. The data on the SDA pin is eight bits long, supporting the 7-bit addresses plus the R/W bit. The ADV7189B has 249 subaddresses to enable access to the internal registers. It therefore interprets the first byte as the device address and the second byte as the starting subaddress. The subaddresses auto-increment, allowing data to be written to or read from the starting subaddress. A data transfer is always terminated by a stop condition. The user can also access any unique subaddress register on a one-by-one basis without having to update all the registers.

Stop and start conditions can be detected at any stage during the data transfer. If these conditions are asserted out of sequence with normal read and write operations, they cause an immediate jump to the idle condition. During a given SCLK high period, the user should only issue one start condition, one stop condition, or a single stop condition followed by a single start condition. If an invalid subaddress is issued by the user, the ADV7189B does not issue an acknowledge and returns to the idle condition.

If in auto-increment mode the user exceeds the highest subaddress, the following action is taken:

1. In read mode, the highest subaddress register contents continue to be output until the master device issues a no-acknowledge. This indicates the end of a read. A no-acknowledge condition is when the SDA line is not pulled low on the ninth pulse.
2. In write mode, the data for the invalid byte is not loaded into any subaddress register, a no acknowledge is issued by the ADV7189B, and the part returns to the idle condition.

Figure 39. Bus Data Transfer

Figure 40. Read and Write Sequence

REGISTER ACCESSES

The MPU can write to or read from most of the ADV7189B's registers, excepting the registers that are read-only or write-only. The subaddress register determines which register the next read or write operation accesses. All communications with the part through the bus start with an access to the subaddress register. Then, a read/write operation is performed from/to the target address, which then increments to the next address until a stop command on the bus is performed.

REGISTER PROGRAMMING

This section describes the configuration of each register. The communications register is an 8-bit, write-only register. After the part has been accessed over the bus and a read/write operation is selected, the subaddress is set up. The subaddress register determines to/from which register the operation takes place. Table 82 lists the various operations under the control of the Subaddress register for the control port.

Register Select (SR7–SR0)

These bits are set up to point to the required starting address.

I²C SEQUENCER

An I²C sequencer is used when a parameter exceeds eight bits, and is therefore distributed over two or more I²C registers, for example, HSB[11:0].

When such a parameter is changed using two or more I²C write operations, the parameter can hold an invalid value for the time between the first I²C being completed and the last I²C being completed. In other words, the top bits of the parameter can already hold the new value while the remaining bits of the parameter still hold the previous value.

To avoid this problem, the I²C sequencer holds the already updated bits of the parameter in local memory; all bits of the parameter are updated together once the last register write operation has completed.

The correct operation of the I²C sequencer relies on the following:

- All I²C registers for the parameter in question must be written to in order of ascending addresses. For example, for HSB[10:0], write to Address 0x34 first followed by 0x35.
- No other I²C taking place between the two (or more) I²C writes for the sequence. For example, for HSB[10:0], write to Address 0x34 first immediately followed by 0x35.

					1	1	1	0			Not used	
					1	1	1	1			Not used	
		TOD. Three-State Output Drivers. This bit allows the user to three-state the output drivers: P[19:0], HS, VS, FIELD, and SFL.		0							Output pins enabled	See also TIM_OE and TRI_LLC
				1							Drivers three-stated	
		VBI_EN. Allows VBI data (Lines 1 to 21) to be passed through with only a minimum amount of filtering performed.		0							All lines filtered and scaled	
				1							Only active video region filtered	
0x04	Extended Output Control	RANGE. Allows the user to select the range of output values. Can be BT656-compliant, or can fill the whole accessible number range.							0	16 < Y < 235, 16 < C < 240	ITU-R BT.656	
									1	1 < Y < 254, 1 < C < 254	Extended range	
		EN_SFL_PIN							0	SFL output is disabled	SFL output enables encoder and decoder to be connected directly.	
									1	SFL information output on the SFL pin		
		BL_C_VBI. Blank Chroma during VBI. If set, enables data in the VBI region to be passed through the decoder undistorted.						0		Decode and output color	During VBI	
								1		Blank Cr and Cb		
		TIM_OE. Timing signals output enable.					0			HS, VS, F three-stated	Controlled by TOD	
							1			HS, VS, F forced active		
			Reserved			x	x					
			Reserved		1							
	BT656-4. Allows the user to select an output mode compatible with ITU-R BT656-3/4.		0						BT656-3-compatible			
			1						BT656-4-compatible			

ADV7189B

Subaddress	Register	Bit Description	Bits							Comments	Notes	
			7	6	5	4	3	2	1			0
0x07	Autodetect Enable	AD_PAL_EN. PAL B/G/I/H autodetect enable.								0	Disable

		AD_P60_EN. PAL 60 autodetect enable.				0					Disable	
						1					Enable	
		AD_N443_EN. NTSC443 autodetect enable.			0						Disable	
					1						Enable	
		AD_SECAM_EN. SECAM autodetect enable.		0							Disable	
				1							Enable	
AD_SEC525_EN. SECAM 525 autodetect enable.	0								Disable			
	1								Enable			
0x08	Contrast Register	CON[7:0]. Contrast adjust. This is the user control for contrast adjustment.	1	0	0	0	0	0	0	0	Luma gain = 1	0x00 Gain = 0 0x80 Gain = 1; 0xFF Gain = 2
0x09	Reserved	Reserved	1	0	0	0	0	0	0	0		
0x0A	Brightness Register	BRI[7:0]. This register controls the brightness of the video signal.	0	0	0	0	0	0	0	0		0x00 = 0IRE 0x7F = +100IRE 0x80 = −100IRE
0x0B	Hue Register	HUE[7:0]. This register contains the value for the color hue adjustment.	0	0	0	0	0	0	0	0		Hue range = −90° to +90°
0x0C	Default Value Y	DEF_VAL_EN. Default value enable.								0	Free-run mode dependent on DEF_VAL_AUTO_EN	
										1	Force Free-run mode on and output blue screen	
		DEF_VAL_AUTO_EN. Default value.								0	Disable Free-run mode	When lock is lost, Free-run mode can be enabled to output stable timing, clock, and a set color.
									1	Enable Automatic Free-run mode (blue screen)		
0x0D	Default Value C	DEF_Y[5:0]. Default value Y. This register holds the Y default value.	0	0	1	1	0	1			Y[7:0] = {DEF_Y[5:0],0,0}	Default Y value output in Free-run mode.
0x0D	Default Value C	DEF_C[7:0]. Default value C. The Cr and Cb default values are defined in this register.	0	1	1	1	1	1	0	0	Cr[7:0] = DEF_C[7:4],0,0,0,0 Cb[7:0] = DEF_C[3:0],0,0,0,0	Default Cb/Cr value output in Free-run mode. Default values give blue screen output.
0x0E	ADI Control	Reserved				0	0	0	0	0	Set as default	
		SUB_USR_EN. Enables the user to access the Interrupt map.			0						Access User Reg Map	See Figure 38
				1							Access Interrupt Reg Map	
		Reserved	0	0							Set as default	

Subaddress	Register	Bit Description	Bits							Comments	Notes		
			7	6	5	4	3	2	1			0	
0x0F	Power Management	Reserved							0	0	Set to default		
		PDBP. Power-down bit priority selects between PWRDN bit or PIN.						0			Chip power down controlled by pin		
								1			Bit has priority (pin disregarded)		
		Reserved				0	0				Set to default		
		PWRDN. Power down places the decoder in a full power-down mode.			0						System functional		
					1							Powered down	See PDBP, 0x0F Bit 2.
		Reserved		0							Set to default		
		RES. Chip reset loads all I ² C bits with default values.	0								Normal operation		
1									Start reset sequence	Executing reset takes approx. 2 ms. This bit is self-clearing.			
0x10	Status Register 1. Read-Only.	IN_LOCK								x	In lock (right now) = 1	Provides information about the internal status of the decoder.	
		LOST_LOCK								x	Lost lock (since last read) = 1		
		FSC_LOCK							x		F _{SC} lock (right now) = 1		
		FOLLOW_PW					x				Peak white AGC mode active = 1		
		AD_RESULT[2:0]. Autodetection result reports the standard of the Input video.		0	0	0						NTSM-MJ	Detected standard.
				0	0	1						NTSC-443	
				0	1	0						PAL-M	
				0	1	1						PAL-60	
				1	0	0						PAL-BGHID	
				1	0	1						SECAM	
				1	1	0						PAL combination N	
				1	1	1						SECAM 525	
		COL_KILL.	x								Color kill is active = 1	Color kill.	
0x11	IDENT Read-Only	IDENT[7:0] Provides identification on the revision of the part.	x	x	x	x	x	x	x	x		ADV7189B = 0x13	
0x12	Status Register 2. Read-Only.	MVCS DET								x	MV color striping detected	1 = Detected	
		MVCS T3								x	MV color striping type	0 = Type 2, 1 = Type 3	
		MV PS DET							x		MV pseudo sync detected	1 = Detected	
		MV AGC DET						x			MV AGC pulses detected	1 = Detected	
		LL NSTD				x					Nonstandard line length	1 = Detected	
		FSC NSTD			x						Fsc frequency nonstandard	1 = Detected	
		Reserved	x	x									
0x13	Status Register 3. Read-Only.	INST_HLOCK								x	1 = horizontal lock achieved	Unfiltered	
		GEMD								x	1 = Gemstar data detected		
		SD_OP_50HZ							x		SD 60 Hz detected	SD Field rate detect	
		Reserved						x			SD 50 Hz detected		
		FREE_RUN_ACT					x				1 = Free-run mode active	Blue screen output	
		STD FLD_LEN			x						1 = Field length standard	Correct Field length found	
		INTERLACED		x							1 = Interlaced video detected	Field sequence found	
		PAL_SW_LOCK	x								1 = Swinging burst detected	Reliable swinging burst sequence	
0x14	Analog Clamp Control	Reserved					0	0	1	0	Set to default		
		CCLEN. Current clamp enable allows the user to switch off the current sources in the analog front.				0					Current sources switched off		
						1					Current sources enabled		
		Reserved	0	0	0						Set to default		

ADV7189B

Subaddress	Register	Bit Description	Bits								Comments	Notes
			7	6	5	4	3	2	1	0		
0x15	Digital Clamp Control 1	Reserved				0	x	x	x	x	Set to default	
		DCT[1:0]. Digital clamp timing determines the time constant of the digital fine clamp circuitry.		0	0						Slow (TC = 1 sec)	
				0	1						Medium (TC = 0.5 sec)	
				1	0						Fast (TC = 0.1 sec)	
				1	1						TC dependent on video

PCB LAYOUT RECOMMENDATIONS

The ADV7189B is a high precision, high speed, mixed-signal device. To achieve the maximum performance from the part, it is important to have a well laid out PCB board. The following is a guide for designing a board using the ADV7189B.

ANALOG INTERFACE INPUTS

Take care when routing the inputs on the PCB. Track lengths should be kept to a minimum, and $75\ \Omega$ trace impedances should be used when possible. Trace impedances other than $75\ \Omega$ increase the chance of reflections.

POWER SUPPLY DECOUPLING

It is recommended to decouple each power supply pin with $0.1\ \mu\text{F}$ and $10\ \text{nF}$ capacitors. The fundamental idea is to have a decoupling capacitor within about $0.5\ \text{cm}$ of each power pin. Also, avoid placing the capacitor on the opposite side of the PCB board from the ADV7189B, as doing so interposes resistive vias in the path. The bypass capacitors should be located between the power plane and the power pin. Current should flow from the power plane to the capacitor to the power pin. Do not make the power connection between the capacitor and the power pin. Placing a via underneath the $100\ \text{nF}$ capacitor pads, down to the power plane, is generally the best approach (see Figure 41).

Figure 41. Recommend Power Supply Decoupling

It is particularly important to maintain low noise and good stability of PVDD. Careful attention must be paid to regulation, filtering, and decoupling. It is highly desirable to provide separate regulated supplies for each of the analog circuitry groups (AVDD, DVDD, DVDDIO, and PVDD).

Some graphic controllers use substantially different levels of power when active (during active picture time) and when idle (during horizontal and vertical sync periods). This can result in a measurable change in the voltage supplied to the analog supply regulator, which can, in turn, produce changes in the regulated analog supply voltage. This is mitigated by regulating the analog supply, or at least PVDD, from a different, cleaner, power source, for example, from a $12\ \text{V}$ supply.

It is recommended to use a single ground plane for the entire board. This ground plane should have a space between the analog and digital sections of the PCB (see Figure 42).

Figure 42. PCB Ground Layout

Experience has repeatedly shown that noise performance is the same or better with a single ground plane. Using multiple ground planes can be detrimental because each separate ground plane is smaller, and long ground loops can result.

In some cases, using separate ground planes is unavoidable. For these cases, it is recommended to place a single ground plane under the ADV7189B. The location of the split should be under the ADV7189B. For this case, it is even more important to place components wisely because the current loops are much longer (current takes the path of least resistance). Here is an example of a current loop: power plane to ADV7189B to digital output trace to digital data receiver to digital ground plane to analog ground plane.

PLL

Place the PLL loop filter components as close as possible to the ELPF pin. Do not place any digital or other high frequency traces near these components. Use the values suggested in the data sheet with tolerances of 10% or less.

DIGITAL OUTPUTS (BOTH DATA AND CLOCKS)

Try to minimize the trace length that digital outputs have to drive. Longer traces have higher capacitance, which require more current, which causes more internal digital noise. Shorter traces reduce the possibility of reflections.

Adding a $30\ \Omega$ to $50\ \Omega$ series resistor can suppress reflections, reduce EMI, and reduce the current spikes inside the ADV7189B. If series resistors are used, place them as close as possible to the ADV7189B pins. However, try not to add vias or extra length to the output trace to make the resistors closer.

If possible, limit the capacitance that each of the digital outputs drives to less than $15\ \text{pF}$. This can easily be accomplished by keeping traces short and by connecting the outputs to only one device. Loading the outputs with excessive capacitance increases the current transients inside the ADV7189B, creating more digital noise on its power supplies.

DIGITAL INPUTS

The digital inputs on the ADV7189B are designed to work with 3.3 V signals, and are not tolerant of 5 V signals. Extra components are needed if 5 V logic signals are required to be applied to the decoder.

ANTIALIASING FILTERS

For inputs from some video sources that are not bandwidth limited, signals outside the video band can alias back into the video band during A/D conversion and appear as noise on the output video. The ADV7189B oversamples the analog inputs by a factor of 4. This 54 MHz sampling frequency reduces the requirement for an input filter; for optimal performance it is recommended that an antialiasing filter be employed. The recommended low cost circuit for implementing this buffer and filter circuit for all analog input signals is shown in Figure 45.

The buffer is a simple emitter-follower using a single npn transistor. The antialiasing filter is implemented using passive components. The passive filter is a third-order Butterworth filter with a -3 dB point of 9 MHz. The frequency response of the passive filter is shown in Figure 43. The flat pass band up to 6 MHz is essential. The attenuation of the signal at the output of the filter due to the voltage divider of R24 and R63 is compensated for in the ADV7189B part using the automatic gain control. The ac-coupling capacitor at the input to the buffer creates a high-pass filter with the biasing resistors for the transistor. This filter has a cut-off of

$$\{2 \times \pi \times (R39 || R89) \times C93\}^{-1} = 0.62 \text{ Hz}$$

It is essential the cutoff of this filter is less than 1 Hz to ensure correct operation of the internal clamps within the part. These clamps ensure that the video stays within the 5 V range of the op amp used.

Figure 43. Third-Order Butterworth Filter Response

CRYSTAL LOAD CAPACITOR VALUE SELECTION

Figure 44 shows an example reference clock circuit for the ADV7189B. Special care must be taken when using a crystal circuit to generate the reference clock for the ADV7189B. Small variations in reference clock frequency can cause autodetection issues and impair the ADV7189B performance.

Note: Load capacitor values are dependent on crystal attributes.

The load capacitance given in a crystal data sheet specifies the parallel resonance frequency within the tolerance at 25°C. It is therefore important to design a circuit that matches the load capacitance in order to achieve the frequency stipulated by the manufacturer. For detailed crystal circuit design and optimization, an application note on crystal design considerations is available for further reference.

Figure 44. Crystal Circuit

Use the following guidelines to ensure correct operation:

- Use the correct frequency crystal, which is 28.63636 MHz. Tolerance should be 50 ppm or better.
- Use a parallel-resonant crystal.
- Place a 1 MΩ shunt resistor across pins XTAL1 and XTAL2 as is shown in Figure 45.
- Know the C_{LOAD} for the crystal part number selected. The value of Capacitors C1 and C2 must match C_{LOAD} for the specific crystal part number in the user's system.
- To find C_{LOAD} use the following guideline:

$$C1 = C2 = C$$

$$C = 2(C_{LOAD} - C_s) - C_{pg}$$

Where C_{pg} is the pin to ground capacitance.
Approximately 4 pF to 10 pF.

C_s is the PCB stray capacitance.
Approximately 2 pF to 3pF.

For example:

$$C_{LOAD} = 30 \text{ pF}$$

$$C = 2(30 - 3) - 4$$

$$= 50 \text{ pF}$$

Therefore two 47 pF capacitors can be chosen for C1 and C2.

TYPICAL CIRCUIT CONNECTION

Examples of how to connect the ADV7189B video decoder are shown in Figure 45 and Figure 46. For a detailed schematic diagram for the ADV7189B, refer to the ADV7189B evaluation note.

¹ The ADV7189B is a Pb-free, environmentally friendly product. It is manufactured using the most up-to-date materials and processes. The coating on the leads of each device is 100% pure Sn electroplate. The device is suitable for Pb-free applications, and can withstand surface-mount soldering at up to 255°C (±5°C). In addition, it is backward-compatible with conventional SnPb soldering processes. This means the electroplated Sn coating can be soldered with Sn/Pb solder pastes at conventional reflow temperatures of 220°C to 235°C.

² Z = Pb-free part.
