About This Document

This data sheet provides reference information for the LM3S2432 microcontroller, describing the functional blocks of the system-on-chip (SoC) device designed around the ARM® Cortex™-M3 core.

Audience

This manual is intended for system software developers, hardware designers, and application developers.

About This Manual

This document is organized into sections that correspond to each major feature.

Related Documents

The following documents are referenced by the data sheet, and available on the documentation CD or from the Luminary Micro web site at www.luminarymicro.com:

- ARM® Cortex™-M3 Technical Reference Manual
- ARM® CoreSight Technical Reference Manual
- ARM® v7-M Architecture Application Level Reference Manual

The following related documents are also referenced:

IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture

This documentation list was current as of publication date. Please check the Luminary Micro web site for additional documentation, including application notes and white papers.

Documentation Conventions

This document uses the conventions shown in Table 1 on page 19.

Table 1. Documentation Conventions

Notation	Meaning		
General Register Notation			
REGISTER	APB registers are indicated in uppercase bold. For example, PBORCTL is the Power-On and Brown-Out Reset Control register. If a register name contains a lowercase n, it represents more than one register. For example, SRCRn represents any (or all) of the three Software Reset Control registers: SRCR0 , SRCR1 , and SRCR2 .		
bit	A single bit in a register.		
bit field	Two or more consecutive and related bits.		
offset 0xnnn	A hexadecimal increment to a register's address, relative to that module's base address as specified in "Memory Map" on page 41.		
Register N	Registers are numbered consecutively throughout the document to aid in referencing them. The register number has no meaning to software.		

Notation	Meaning	
reserved	Register bits marked <i>reserved</i> are reserved for future use. In most cases, reserved bits are set to 0; however, user software should not rely on the value of a reserved bit. To provide software compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.	
уу:хх	The range of register bits inclusive from xx to yy. For example, 31:15 means bits 15 through 31 in that register.	
Register Bit/Field Types	This value in the register bit diagram indicates whether software running on the controller can change the value of the bit field.	
RC	Software can read this field. The bit or field is cleared by hardware after reading the bit/field.	
RO	Software can read this field. Always write the chip reset value.	
R/W	Software can read or write this field.	
R/W1C	Software can read or write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged.	
	This register type is primarily used for clearing interrupt status bits where the read operation provides the interrupt status and the write of the read value clears only the interrupts being reported at the time the register was read.	
W1C	Software can write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. A read of the register returns no meaningful data.	
	This register is typically used to clear the corresponding bit in an interrupt register.	
WO	Only a write by software is valid; a read of the register returns no meaningful data.	
Register Bit/Field Reset Value	This value in the register bit diagram shows the bit/field value after any reset, unless noted.	
0	Bit cleared to 0 on chip reset.	
1	Bit set to 1 on chip reset.	
-	Nondeterministic.	
Pin/Signal Notation		
[]	Pin alternate function; a pin defaults to the signal without the brackets.	
pin	Refers to the physical connection on the package.	
signal	Refers to the electrical signal encoding of a pin.	
assert a signal	Change the value of the signal from the logically False state to the logically True state. For active High signals, the asserted signal value is 1 (High); for active Low signals, the asserted signal value is 0 (Low). The active polarity (High or Low) is defined by the signal name (see SIGNAL and SIGNAL below).	
deassert a signal	Change the value of the signal from the logically True state to the logically False state.	
SIGNAL	Signal names are in uppercase and in the Courier font. An overbar on a signal name indicates that it is active Low. To assert SIGNAL is to drive it Low; to deassert SIGNAL is to drive it High.	
SIGNAL	Signal names are in uppercase and in the Courier font. An active High signal has no overbar. To assert SIGNAL is to drive it High; to deassert SIGNAL is to drive it Low.	
Numbers		
X	An uppercase X indicates any of several values is allowed, where X can be any legal pattern. For example, a binary value of 0X00 can be either 0100 or 0000, a hex value of 0xX is 0x0 or 0x1, and so on.	
0x	Hexadecimal numbers have a prefix of 0x. For example, 0x00FF is the hexadecimal number FF. All other numbers within register tables are assumed to be binary. Within conceptual information, binary numbers are indicated with a b suffix, for example, 1011b, and decimal numbers are written without a prefix or suffix.	

1 Architectural Overview

The Luminary Micro Stellaris[®] family of microcontrollers—the first ARM® Cortex[™]-M3 based controllers—brings high-performance 32-bit computing to cost-sensitive embedded microcontroller applications. These pioneering parts deliver customers 32-bit performance at a cost equivalent to legacy 8- and 16-bit devices, all in a package with a small footprint.

The Stellaris[®] family offers efficient performance and extensive integration, favorably positioning the device into cost-conscious applications requiring significant control-processing and connectivity capabilities. The Stellaris[®] LM3S1000 series extends the Stellaris[®] family with larger on-chip memories, enhanced power management, and expanded I/O and control capabilities. The Stellaris[®] LM3S2000 series, designed for Controller Area Network (CAN) applications, extends the Stellaris family with Bosch CAN networking technology, the golden standard in short-haul industrial networks. The Stellaris[®] LM3S2000 series also marks the first integration of CAN capabilities with the revolutionary Cortex-M3 core. The Stellaris[®] LM3S6000 series combines both a 10/100 Ethernet Media Access Control (MAC) and Physical (PHY) layer, marking the first time that integrated connectivity is available with an ARM Cortex-M3 MCU and the only integrated 10/100 Ethernet MAC and PHY available in an ARM architecture MCU. The Stellaris[®] LM3S8000 series combines Bosch Controller Area Network technology with both a 10/100 Ethernet Media Access Control (MAC) and Physical (PHY) layer.

The LM3S2432 microcontroller is targeted for industrial applications, including remote monitoring, electronic point-of-sale machines, test and measurement equipment, network appliances and switches, factory automation, HVAC and building control, gaming equipment, motion control, medical instrumentation, and fire and security.

In addition, the LM3S2432 microcontroller offers the advantages of ARM's widely available development tools, System-on-Chip (SoC) infrastructure IP applications, and a large user community. Additionally, the microcontroller uses ARM's Thumb®-compatible Thumb-2 instruction set to reduce memory requirements and, thereby, cost. Finally, the LM3S2432 microcontroller is code-compatible to all members of the extensive Stellaris® family; providing flexibility to fit our customers' precise needs.

Luminary Micro offers a complete solution to get to market quickly, with evaluation and development boards, white papers and application notes, an easy-to-use peripheral driver library, and a strong support, sales, and distributor network.

1.1 Product Features

The LM3S2432 microcontroller includes the following product features:

- 32-Bit RISC Performance
 - 32-bit ARM® Cortex™-M3 v7M architecture optimized for small-footprint embedded applications
 - System timer (SysTick), providing a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism
 - Thumb®-compatible Thumb-2-only instruction set processor core for high code density
 - 50-MHz operation
 - Hardware-division and single-cycle-multiplication

- Integrated Nested Vectored Interrupt Controller (NVIC) providing deterministic interrupt handling
- 30 interrupts with eight priority levels
- Memory protection unit (MPU), providing a privileged mode for protected operating system functionality
- Unaligned data access, enabling data to be efficiently packed into memory
- Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control

Internal Memory

- 96 KB single-cycle flash
 - User-managed flash block protection on a 2-KB block basis
 - · User-managed flash data programming
 - User-defined and managed flash-protection block
- 32 KB single-cycle SRAM

General-Purpose Timers

- Three General-Purpose Timer Modules (GPTM), each of which provides two 16-bit timers.
 Each GPTM can be configured to operate independently:
 - As a single 32-bit timer
 - As one 32-bit Real-Time Clock (RTC) to event capture
 - For Pulse Width Modulation (PWM)
 - To trigger analog-to-digital conversions
- 32-bit Timer modes
 - · Programmable one-shot timer
 - · Programmable periodic timer
 - Real-Time Clock when using an external 32.768-KHz clock as the input
 - User-enabled stalling in periodic and one-shot mode when the controller asserts the CPU Halt flag during debug
 - · ADC event trigger
- 16-bit Timer modes
 - General-purpose timer function with an 8-bit prescaler
 - · Programmable one-shot timer

- · Programmable periodic timer
- · User-enabled stalling when the controller asserts CPU Halt flag during debug
- ADC event trigger
- 16-bit Input Capture modes
 - · Input edge count capture
 - Input edge time capture
- 16-bit PWM mode
 - · Simple PWM mode with software-programmable output inversion of the PWM signal
- ARM FiRM-compliant Watchdog Timer
 - 32-bit down counter with a programmable load register
 - Separate watchdog clock with an enable
 - Programmable interrupt generation logic with interrupt masking
 - Lock register protection from runaway software
 - Reset generation logic with an enable/disable
 - User-enabled stalling when the controller asserts the CPU Halt flag during debug
- Controller Area Network (CAN)
 - Supports CAN protocol version 2.0 part A/B
 - Bit rates up to 1Mb/s
 - 32 message objects, each with its own identifier mask
 - Maskable interrupt
 - Disable automatic retransmission mode for TTCAN
 - Programmable loop-back mode for self-test operation
- Synchronous Serial Interface (SSI)
 - Master or slave operation
 - Programmable clock bit rate and prescale
 - Separate transmit and receive FIFOs, 16 bits wide, 8 locations deep
 - Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
 - Programmable data frame size from 4 to 16 bits

Internal loopback test mode for diagnostic/debug testing

UART

- Two fully programmable 16C550-type UARTs with IrDA support
- Separate 16x8 transmit (TX) and 16x12 receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable baud-rate generator with fractional divider
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- False-start-bit detection
- Line-break generation and detection

ADC

- Single- and differential-input configurations
- Three 10-bit channels (inputs) when used as single-ended inputs
- Sample rate of 250 thousand samples/second
- Flexible, configurable analog-to-digital conversion
- Four programmable sample conversion sequences from one to eight entries long, with corresponding conversion result FIFOs
- Each sequence triggered by software or internal event (timers, analog comparators, PWM or GPIO)
- On-chip temperature sensor

Analog Comparators

- Two independent integrated analog comparators
- Configurable for output to: drive an output pin, generate an interrupt, or initiate an ADC sample sequence
- Compare external pin input to external pin input or to internal programmable voltage reference

I²C

- Master and slave receive and transmit operation with transmission speed up to 100 Kbps in Standard mode and 400 Kbps in Fast mode
- Interrupt generation

 Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode

PWM

- One PWM generator blocks, each with one 16-bit counter, two comparators, a PWM generator, and a dead-band generator
- One 16-bit counter
 - · Runs in Down or Up/Down mode
 - · Output frequency controlled by a 16-bit load value
 - · Load value updates can be synchronized
 - · Produces output signals at zero and load value
- Two PWM comparators
 - Comparator value updates can be synchronized
 - · Produces output signals on match
- PWM generator
 - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
 - Produces two independent PWM signals
- Dead-band generator
 - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
 - · Can be bypassed, leaving input PWM signals unmodified
- Flexible output control block with PWM output enable of each PWM signal
 - PWM output enable of each PWM signal
 - Optional output inversion of each PWM signal (polarity control)
 - Optional fault handling for each PWM signal
 - Synchronization of timers in the PWM generator blocks
 - Synchronization of timer/comparator updates across the PWM generator blocks
 - Interrupt status summary of the PWM generator blocks
- Can initiate an ADC sample sequence
- GPIOs
 - 5-34 GPIOs, depending on configuration

- 5-V-tolerant input/outputs
- Programmable interrupt generation as either edge-triggered or level-sensitive
- Bit masking in both read and write operations through address lines
- Can initiate an ADC sample sequence
- Programmable control for GPIO pad configuration:
 - Weak pull-up or pull-down resistors
 - 2-mA, 4-mA, and 8-mA pad drive
 - Slew rate control for the 8-mA drive
 - Open drain enables
 - · Digital input enables

Power

- On-chip Low Drop-Out (LDO) voltage regulator, with programmable output user-adjustable from 2.25 V to 2.75 V
- Low-power options on controller: Sleep and Deep-sleep modes
- Low-power options for peripherals: software controls shutdown of individual peripherals
- User-enabled LDO unregulated voltage detection and automatic reset
- 3.3-V supply brown-out detection and reporting via interrupt or reset
- Flexible Reset Sources
 - Power-on reset (POR)
 - Reset pin assertion
 - Brown-out (BOR) detector alerts to system power drops
 - Software reset
 - Watchdog timer reset
 - Internal low drop-out (LDO) regulator output goes unregulated
- Additional Features
 - Six reset sources
 - Programmable clock source control
 - Clock gating to individual peripherals for power savings
 - IEEE 1149.1-1990 compliant Test Access Port (TAP) controller

- Debug access via JTAG and Serial Wire interfaces
- Full JTAG boundary scan
- Industrial-range 100-pin RoHS-compliant LQFP package

1.2 Target Applications

- Remote monitoring
- Electronic point-of-sale (POS) machines
- Test and measurement equipment
- Network appliances and switches
- Factory automation
- HVAC and building control
- Gaming equipment
- Motion control
- Medical instrumentation
- Fire and security
- Power and energy
- Transportation

1.3 High-Level Block Diagram

Figure 1-1 on page 28 represents the full set of features in the Stellaris[®] 2000 series of devices; not all features may be available on the LM3S2432 microcontroller.

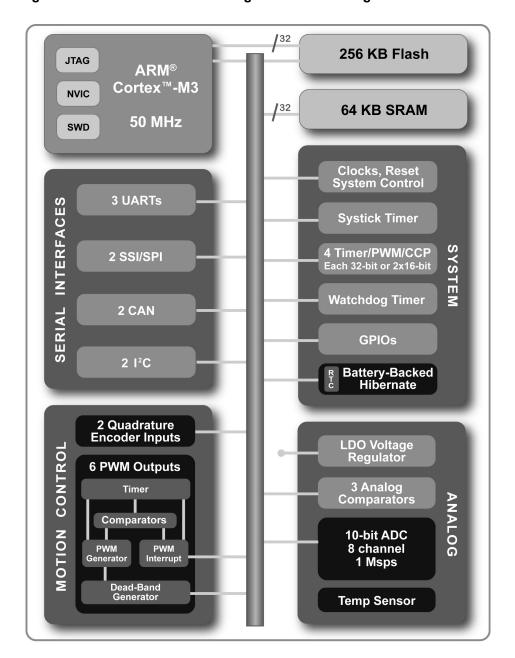

Figure 1-1. Stellaris® 2000 Series High-Level Block Diagram

1.4 Functional Overview

The following sections provide an overview of the features of the LM3S2432 microcontroller. The page number in parenthesis indicates where that feature is discussed in detail. Ordering and support information can be found in "Ordering and Contact Information" on page 519.

1.4.1 ARM Cortex™-M3

1.4.1.1 Processor Core (see page 35)

All members of the Stellaris[®] product family, including the LM3S2432 microcontroller, are designed around an ARM Cortex[™]-M3 processor core. The ARM Cortex-M3 processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low-power consumption, while delivering outstanding computational performance and exceptional system response to interrupts.

"ARM Cortex-M3 Processor Core" on page 35 provides an overview of the ARM core; the core is detailed in the *ARM*® *Cortex*™-*M3 Technical Reference Manual*.

1.4.1.2 System Timer (SysTick)

Cortex-M3 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer which fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter. Software can use this to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNTFLAG bit-field
 in the control and status register can be used to determine if an action completed within a set
 duration, as part of a dynamic clock management control loop.

1.4.1.3 Nested Vectored Interrupt Controller (NVIC)

The LM3S2432 controller includes the ARM Nested Vectored Interrupt Controller (NVIC) on the ARM Cortex-M3 core. The NVIC and Cortex-M3 prioritize and handle all exceptions. All exceptions are handled in Handler Mode. The processor state is automatically stored to the stack on an exception, and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, which enables efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration. Software can set eight priority levels on 7 exceptions (system handlers) and 30 interrupts.

"Interrupts" on page 43 provides an overview of the NVIC controller and the interrupt map. Exceptions and interrupts are detailed in the *ARM*® *Cortex*™-*M3 Technical Reference Manual*.

1.4.2 Motor Control Peripherals

To enhance motor control, the LM3S2432 controller features Pulse Width Modulation (PWM) outputs.

1.4.2.1 PWM

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

On the LM3S2432, PWM motion control functionality can be achieved through:

- Dedicated, flexible motion control hardware using the PWM pins
- The motion control features of the general-purpose timers using the CCP pins

PWM Pins (see page 435)

The LM3S2432 PWM module consists of one PWM generator blocks and a control block. Each PWM generator block contains one timer (16-bit down or up/down counter), two comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

Each PWM generator block produces two PWM signals that can either be independent signals or a single pair of complementary signals with dead-band delays inserted. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins.

CCP Pins (see page 183)

The General-Purpose Timer Module's CCP (Capture Compare PWM) pins are software programmable to support a simple PWM mode with a software-programmable output inversion of the PWM signal.

1.4.3 Analog Peripherals

To handle analog signals, the LM3S2432 microcontroller offers an Analog-to-Digital Converter (ADC).

For support of analog signals, the LM3S2432 microcontroller offers two analog comparators.

1.4.3.1 ADC (see page 236)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number.

The LM3S2432 ADC module features 10-bit conversion resolution and supports three input channels, plus an internal temperature sensor. Four buffered sample sequences allow rapid sampling of up to eight analog input sources without controller intervention. Each sample sequence provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequence priority.

1.4.3.2 Analog Comparators (see page 423)

An analog comparator is a peripheral that compares two analog voltages, and provides a logical output that signals the comparison result.

The LM3S2432 microcontroller provides two independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

A comparator can compare a test voltage against any one of these voltages:

- An individual external reference voltage
- A shared single external reference voltage
- A shared internal reference voltage

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering

logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

1.4.4 Serial Communications Peripherals

The LM3S2432 controller supports both asynchronous and synchronous serial communications with:

- Two fully programmable 16C550-type UARTs
- One SSI module
- One I²C module
- One CAN unit

1.4.4.1 UART (see page 269)

A Universal Asynchronous Receiver/Transmitter (UART) is an integrated circuit used for RS-232C serial communications, containing a transmitter (parallel-to-serial converter) and a receiver (serial-to-parallel converter), each clocked separately.

The LM3S2432 controller includes two fully programmable 16C550-type UARTs that support data transfer speeds up to 460.8 Kbps. (Although similar in functionality to a 16C550 UART, it is not register-compatible.) In addition, each UART is capable of supporting IrDA.

Separate 16x8 transmit (TX) and 16x12 receive (RX) FIFOs reduce CPU interrupt service loading. The UART can generate individually masked interrupts from the RX, TX, modem status, and error conditions. The module provides a single combined interrupt when any of the interrupts are asserted and are unmasked.

1.4.4.2 SSI (see page 310)

Synchronous Serial Interface (SSI) is a four-wire bi-directional communications interface.

The LM3S2432 controller includes one SSI module that provides the functionality for synchronous serial communications with peripheral devices, and can be configured to use the Freescale SPI, MICROWIRE, or TI synchronous serial interface frame formats. The size of the data frame is also configurable, and can be set between 4 and 16 bits, inclusive.

The SSI module performs serial-to-parallel conversion on data received from a peripheral device, and parallel-to-serial conversion on data transmitted to a peripheral device. The TX and RX paths are buffered with internal FIFOs, allowing up to eight 16-bit values to be stored independently.

The SSI module can be configured as either a master or slave device. As a slave device, the SSI module can also be configured to disable its output, which allows a master device to be coupled with multiple slave devices.

The SSI module also includes a programmable bit rate clock divider and prescaler to generate the output serial clock derived from the SSI module's input clock. Bit rates are generated based on the input clock and the maximum bit rate is determined by the connected peripheral.

1.4.4.3 I²C (see page 347)

The Inter-Integrated Circuit (I²C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL).

The I²C bus interfaces to external I²C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I²C bus may also be used for system testing and diagnostic purposes in product development and manufacture.

The LM3S2432 controller includes one I²C module that provides the ability to communicate to other IC devices over an I²C bus. The I²C bus supports devices that can both transmit and receive (write and read) data.

Devices on the I²C bus can be designated as either a master or a slave. The I²C module supports both sending and receiving data as either a master or a slave, and also supports the simultaneous operation as both a master and a slave. The four I²C modes are: Master Transmit, Master Receive, Slave Transmit, and Slave Receive.

A Stellaris[®] I²C module can operate at two speeds: Standard (100 Kbps) and Fast (400 Kbps).

Both the I²C master and slave can generate interrupts. The I²C master generates interrupts when a transmit or receive operation completes (or aborts due to an error). The I²C slave generates interrupts when data has been sent or requested by a master.

1.4.4.4 Controller Area Network (see page 382)

Controller Area Network (CAN) is a multicast shared serial-bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, now it is used in many embedded control applications (for example, industrial or medical). Bit rates up to 1Mb/s are possible at network lengths below 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kb/s at 500m).

A transmitter sends a message to all CAN nodes (broadcasting). Each node decides on the basis of the identifier received whether it should process the message. The identifier also determines the priority that the message enjoys in competition for bus access. Each CAN message can transmit from 0 to 8 bytes of user information. The LM3S2432 includes one CAN units.

1.4.5 System Peripherals

1.4.5.1 Programmable GPIOs (see page 136)

General-purpose input/output (GPIO) pins offer flexibility for a variety of connections.

The Stellaris[®] GPIO module is composed of eight physical GPIO blocks, each corresponding to an individual GPIO port. The GPIO module is FiRM-compliant (compliant to the ARM Foundation IP for Real-Time Microcontrollers specification) and supports 5-34 programmable input/output pins. The number of GPIOs available depends on the peripherals being used (see "Signal Tables" on page 471 for the signals available to each GPIO pin).

The GPIO module features programmable interrupt generation as either edge-triggered or level-sensitive on all pins, programmable control for GPIO pad configuration, and bit masking in both read and write operations through address lines.

1.4.5.2 Three Programmable Timers (see page 177)

Programmable timers can be used to count or time external events that drive the Timer input pins.

The Stellaris[®] General-Purpose Timer Module (GPTM) contains three GPTM blocks. Each GPTM block provides two 16-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions.

When configured in 32-bit mode, a timer can run as a Real-Time Clock (RTC), one-shot timer or periodic timer. When in 16-bit mode, a timer can run as a one-shot timer or periodic timer, and can extend its precision by using an 8-bit prescaler. A 16-bit timer can also be configured for event capture or Pulse Width Modulation (PWM) generation.

1.4.5.3 Watchdog Timer (see page 213)

A watchdog timer can generate nonmaskable interrupts (NMIs) or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or to the failure of an external device to respond in the expected way.

The Stellaris[®] Watchdog Timer module consists of a 32-bit down counter, a programmable load register, interrupt generation logic, and a locking register.

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

1.4.6 Memory Peripherals

The LM3S2432 controller offers both single-cycle SRAM and single-cycle Flash memory.

1.4.6.1 SRAM (see page 112)

The LM3S2432 static random access memory (SRAM) controller supports 32 KB SRAM. The internal SRAM of the Stellaris[®] devices is located at offset 0x0000.0000 of the device memory map. To reduce the number of time-consuming read-modify-write (RMW) operations, ARM has introduced *bit-banding* technology in the new Cortex-M3 processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

1.4.6.2 Flash (see page 113)

The LM3S2432 Flash controller supports 96 KB of flash memory. The flash is organized as a set of 1-KB blocks that can be individually erased. Erasing a block causes the entire contents of the block to be reset to all 1s. These blocks are paired into a set of 2-KB blocks that can be individually protected. The blocks can be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

1.4.7 Additional Features

1.4.7.1 Memory Map (see page 41)

A memory map lists the location of instructions and data in memory. The memory map for the LM3S2432 controller can be found in "Memory Map" on page 41. Register addresses are given as a hexadecimal increment, relative to the module's base address as shown in the memory map.

The ARM® Cortex™-M3 Technical Reference Manual provides further information on the memory map.

1.4.7.2 JTAG TAP Controller (see page 45)

The Joint Test Action Group (JTAG) port provides a standardized serial interface for controlling the Test Access Port (TAP) and associated test logic. The TAP, JTAG instruction register, and JTAG data registers can be used to test the interconnects of assembled printed circuit boards, obtain

manufacturing information on the components, and observe and/or control the inputs and outputs of the controller during normal operation. The JTAG port provides a high degree of testability and chip-level access at a low cost.

The JTAG port is comprised of the standard five pins: TRST, TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture.

The Luminary Micro JTAG controller works with the ARM JTAG controller built into the Cortex-M3 core. This is implemented by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while Luminary Micro JTAG instructions select the Luminary Micro TDO outputs. The multiplexer is controlled by the Luminary Micro JTAG controller, which has comprehensive programming for the ARM, Luminary Micro, and unimplemented JTAG instructions.

1.4.7.3 System Control and Clocks (see page 56)

System control determines the overall operation of the device. It provides information about the device, controls the clocking of the device and individual peripherals, and handles reset detection and reporting.

1.4.8 Hardware Details

Details on the pins and package can be found in the following sections:

- "Pin Diagram" on page 470
- "Signal Tables" on page 471
- "Operating Characteristics" on page 483
- "Electrical Characteristics" on page 484
- "Package Information" on page 495

2 ARM Cortex-M3 Processor Core

The ARM Cortex-M3 processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts. Features include:

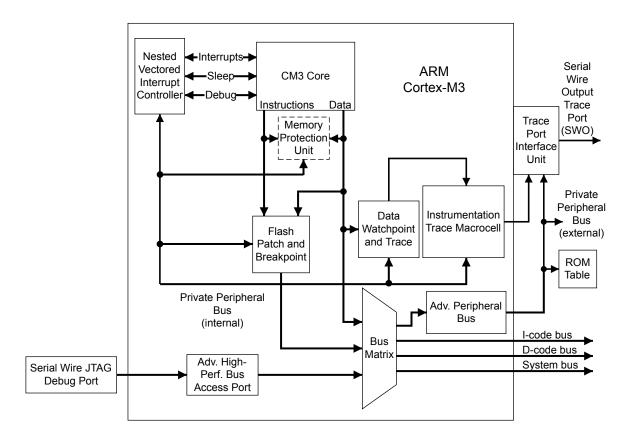

- Compact core.
- Thumb-2 instruction set, delivering the high-performance expected of an ARM core in the memory size usually associated with 8- and 16-bit devices; typically in the range of a few kilobytes of memory for microcontroller class applications.
- Rapid application execution through Harvard architecture characterized by separate buses for instruction and data.
- Exceptional interrupt handling, by implementing the register manipulations required for handling an interrupt in hardware.
- Memory protection unit (MPU) to provide a privileged mode of operation for complex applications.
- Migration from the ARM7TM processor family for better performance and power efficiency.
- Full-featured debug solution with a:
 - Serial Wire JTAG Debug Port (SWJ-DP)
 - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
 - Data Watchpoint and Trigger (DWT) unit for implementing watchpoints, trigger resources, and system profiling
 - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
 - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer

The Stellaris[®] family of microcontrollers builds on this core to bring high-performance 32-bit computing to cost-sensitive embedded microcontroller applications, such as factory automation and control, industrial control power devices, building and home automation, and stepper motors.

For more information on the ARM Cortex-M3 processor core, see the *ARM*® *Cortex*™-*M3 Technical Reference Manual*. For information on SWJ-DP, see the *ARM*® *CoreSight Technical Reference Manual*.

2.1 Block Diagram

Figure 2-1. CPU Block Diagram

2.2 Functional Description

Important: The ARM® Cortex™-M3 Technical Reference Manual describes all the features of an ARM Cortex-M3 in detail. However, these features differ based on the implementation. This section describes the Stellaris® implementation.

Luminary Micro has implemented the ARM Cortex-M3 core as shown in Figure 2-1 on page 36. As noted in the *ARM*® *Cortex*™-*M3 Technical Reference Manual*, several Cortex-M3 components are flexible in their implementation: SW/JTAG-DP, ETM, TPIU, the ROM table, the MPU, and the Nested Vectored Interrupt Controller (NVIC). Each of these is addressed in the sections that follow.

2.2.1 Serial Wire and JTAG Debug

Luminary Micro has replaced the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. This means Chapter 12, "Debug Port," of the *ARM*® *Cortex™-M3 Technical Reference Manual* does not apply to Stellaris[®] devices.

The SWJ-DP interface combines the SWD and JTAG debug ports into one module. See the CoreSight™ Design Kit Technical Reference Manual for details on SWJ-DP.

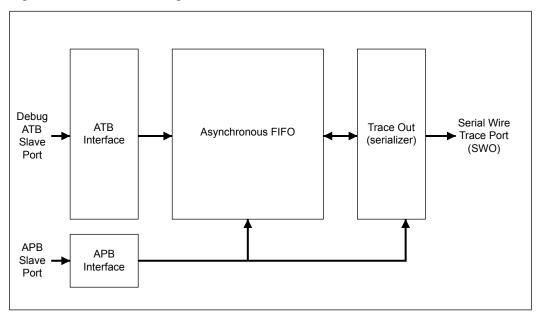

2.2.2 Embedded Trace Macrocell (ETM)

ETM was not implemented in the Stellaris[®] devices. This means Chapters 15 and 16 of the *ARM*® *Cortex*™-*M3 Technical Reference Manual* can be ignored.

2.2.3 Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the Cortex-M3 trace data from the ITM, and an off-chip Trace Port Analyzer. The Stellaris[®] devices have implemented TPIU as shown in Figure 2-2 on page 37. This is similar to the non-ETM version described in the *ARM® Cortex™-M3 Technical Reference Manual*, however, SWJ-DP only provides SWV output for the TPIU.

Figure 2-2. TPIU Block Diagram

2.2.4 ROM Table

The default ROM table was implemented as described in the *ARM*® *Cortex*™-*M3 Technical Reference Manual*.

2.2.5 Memory Protection Unit (MPU)

The Memory Protection Unit (MPU) is included on the LM3S2432 controller and supports the standard ARMv7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

2.2.6 Nested Vectored Interrupt Controller (NVIC)

The Nested Vectored Interrupt Controller (NVIC):

- Facilitates low-latency exception and interrupt handling
- Controls power management
- Implements system control registers

The NVIC supports up to 240 dynamically reprioritizable interrupts each with up to 256 levels of priority. The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts. The NVIC maintains knowledge of the stacked (nested) interrupts to enable tail-chaining of interrupts.

You can only fully access the NVIC from privileged mode, but you can pend interrupts in user-mode if you enable the Configuration Control Register (see the ARM® Cortex™-M3 Technical Reference Manual). Any other user-mode access causes a bus fault.

All NVIC registers are accessible using byte, halfword, and word unless otherwise stated.

All NVIC registers and system debug registers are little endian regardless of the endianness state of the processor.

2.2.6.1 Interrupts

The ARM® Cortex™-M3 Technical Reference Manual describes the maximum number of interrupts and interrupt priorities. The LM3S2432 microcontroller supports 30 interrupts with eight priority levels.

2.2.6.2 System Timer (SysTick)

Cortex-M3 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer which fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter. Software can use this to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNTFLAG bit-field in the control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

Functional Description

The timer consists of three registers:

- A control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status.
- The reload value for the counter, used to provide the counter's wrap value.
- The current value of the counter.

A fourth register, the SysTick Calibration Value Register, is not implemented in the Stellaris[®] devices.

When enabled, the timer counts down from the reload value to zero, reloads (wraps) to the value in the SysTick Reload Value register on the next clock edge, then decrements on subsequent clocks. Writing a value of zero to the Reload Value register disables the counter on the next wrap. When the counter reaches zero, the COUNTFLAG status bit is set. The COUNTFLAG bit clears on reads.

Writing to the Current Value register clears the register and the COUNTFLAG status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

If the core is in debug state (halted), the counter will not decrement. The timer is clocked with respect to a reference clock. The reference clock can be the core clock or an external clock source.

SysTick Control and Status Register

Use the SysTick Control and Status Register to enable the SysTick features. The reset is 0x0000.0000.

Bit/Field	Name	Туре	Reset	Description	
31:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.	
16	COUNTFLAG	R/W	0	Returns 1 if timer counted to 0 since last time this was read. Clears on read by application. If read by the debugger using the DAP, this bit is cleared on read-on if the MasterType bit in the AHB-AP Control Register is set to 0. Otherwise, the COUNTFLAG bit is not changed by the debugger read.	
15:3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.	
2	CLKSOURCE	R/W	0	0 = external reference clock. (Not implemented for Stellaris microcontrollers.)	
				1 = core clock.	
				If no reference clock is provided, it is held at 1 and so gives the same time as the core clock. The core clock must be at least 2.5 times faster than the reference clock. If it is not, the count values are unpredictable.	
1	TICKINT	R/W	0	1 = counting down to 0 pends the SysTick handler.	
				0 = counting down to 0 does not pend the SysTick handler. Software can use the COUNTFLAG to determine if ever counted to 0.	
0	ENABLE	R/W	0	1 = counter operates in a multi-shot way. That is, counter loads with the Reload value and then begins counting down. On reaching 0, it sets the COUNTFLAG to 1 and optionally pends the SysTick handler, based on TICKINT. It then loads the Reload value again, and begins counting. 0 = counter disabled.	

SysTick Reload Value Register

Use the SysTick Reload Value Register to specify the start value to load into the current value register when the counter reaches 0. It can be any value between 1 and 0x00FF.FFFF. A start value of 0 is possible, but has no effect because the SysTick interrupt and COUNTFLAG are activated when counting from 1 to 0.

Therefore, as a multi-shot timer, repeated over and over, it fires every N+1 clock pulse, where N is any value from 1 to 0x00FF.FFFF. So, if the tick interrupt is required every 100 clock pulses, 99 must be written into the RELOAD. If a new value is written on each tick interrupt, so treated as single shot, then the actual count down must be written. For example, if a tick is next required after 400 clock pulses, 400 must be written into the RELOAD.

Bit/Fie	d Name	Туре	Reset	Description
31:24	reserved	RO		Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
23:0	RELOAD	W1C	-	Value to load into the SysTick Current Value Register when the counter reaches 0.

SysTick Current Value Register

Use the SysTick Current Value Register to find the current value in the register.

Bit/Field	Name	Туре	Reset	Description
31:24	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:0	CURRENT	W1C		Current value at the time the register is accessed. No read-modify-write protection is provided, so change with care. This register is write-clear. Writing to it with any value clears the register to 0. Clearing this register also clears the COUNTFLAG bit of the SysTick Control and Status Register.

SysTick Calibration Value Register

The SysTick Calibration Value register is not implemented.

3 Memory Map

The memory map for the LM3S2432 controller is provided in Table 3-1 on page 41.

In this manual, register addresses are given as a hexadecimal increment, relative to the module's base address as shown in the memory map. See also Chapter 4, "Memory Map" in the *ARM*® *Cortex™-M3 Technical Reference Manual*.

Important: In Table 3-1 on page 41, addresses not listed are reserved.

a. All reserved space returns a bus fault when read or written.

b. The unavailable flash will bus fault throughout this range.

c. The unavailable SRAM will bus fault throughout this range.

4 Interrupts

The ARM Cortex-M3 processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions. All exceptions are handled in Handler Mode. The processor state is automatically stored to the stack on an exception, and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, which enables efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration.

Table 4-1 on page 43 lists all the exceptions. Software can set eight priority levels on seven of these exceptions (system handlers) as well as on 30 interrupts (listed in Table 4-2 on page 44).

Priorities on the system handlers are set with the NVIC System Handler Priority registers. Interrupts are enabled through the NVIC Interrupt Set Enable register and prioritized with the NVIC Interrupt Priority registers. You can also group priorities by splitting priority levels into pre-emption priorities and subpriorities. All the interrupt registers are described in Chapter 8, "Nested Vectored Interrupt Controller" in the *ARM® Cortex™-M3 Technical Reference Manual*.

Internally, the highest user-settable priority (0) is treated as fourth priority, after a Reset, NMI, and a Hard Fault. Note that 0 is the default priority for all the settable priorities.

If you assign the same priority level to two or more interrupts, their hardware priority (the lower the position number) determines the order in which the processor activates them. For example, if both GPIO Port A and GPIO Port B are priority level 1, then GPIO Port A has higher priority.

See Chapter 5, "Exceptions" and Chapter 8, "Nested Vectored Interrupt Controller" in the *ARM*® *Cortex*™-*M3 Technical Reference Manual* for more information on exceptions and interrupts.

Note: In Table 4-2 on page 44 interrupts not listed are reserved.

Table 4-1. Exception Types

Exception Type	Position	Priority ^a	Description
-	0	-	Stack top is loaded from first entry of vector table on reset.
Reset	1	-3 (highest)	Invoked on power up and warm reset. On first instruction, drops to lowest priority (and then is called the base level of activation). This is asynchronous.
Non-Maskable Interrupt (NMI)	2	-2	Cannot be stopped or preempted by any exception but reset. This is asynchronous.
			An NMI is only producible by software, using the NVIC Interrupt Control State register.
Hard Fault	3	-1	All classes of Fault, when the fault cannot activate due to priority or the configurable fault handler has been disabled. This is synchronous.
Memory Management	4	settable	MPU mismatch, including access violation and no match. This is synchronous.
			The priority of this exception can be changed.
Bus Fault	5	settable	Pre-fetch fault, memory access fault, and other address/memory related faults. This is synchronous when precise and asynchronous when imprecise.
			You can enable or disable this fault.
Usage Fault	6	settable	Usage fault, such as undefined instruction executed or illegal state transition attempt. This is synchronous.
-	7-10	-	Reserved.
SVCall	11	settable	System service call with SVC instruction. This is synchronous.

Exception Type	Position	Priority ^a	Description
Debug Monitor	12	settable	Debug monitor (when not halting). This is synchronous, but only active when enabled. It does not activate if lower priority than the current activation.
-	13	-	Reserved.
PendSV	14	settable	Pendable request for system service. This is asynchronous and only pended by software.
SysTick	15	settable	System tick timer has fired. This is asynchronous.
Interrupts	16 and above	settable	Asserted from outside the ARM Cortex-M3 core and fed through the NVIC (prioritized). These are all asynchronous. Table 4-2 on page 44 lists the interrupts on the LM3S2432 controller.

a. 0 is the default priority for all the settable priorities.

Table 4-2. Interrupts

Interrupt (Bit in Interrupt Registers)	Description
0	GPIO Port A

5 JTAG Interface

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is comprised of the standard five pins: TRST, TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture.

The Luminary Micro JTAG controller works with the ARM JTAG controller built into the Cortex-M3 core. This is implemented by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while Luminary Micro JTAG instructions select the Luminary Micro TDO outputs. The multiplexer is controlled by the Luminary Micro JTAG controller, which has comprehensive programming for the ARM, Luminary Micro, and unimplemented JTAG instructions.

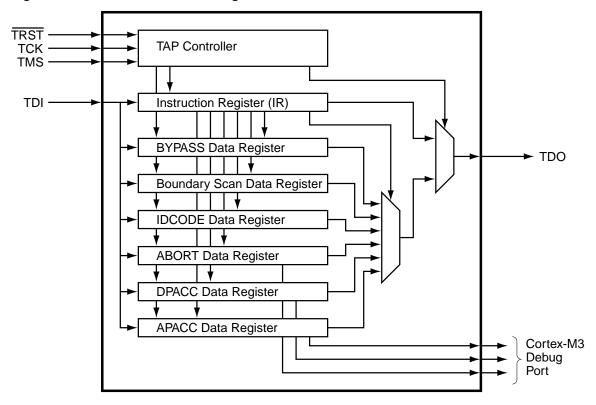

The JTAG module has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions:
 - BYPASS instruction
 - IDCODE instruction
 - SAMPLE/PRELOAD instruction
 - EXTEST instruction
 - INTEST instruction
- ARM additional instructions:
 - APACC instruction
 - DPACC instruction
 - ABORT instruction
- Integrated ARM Serial Wire Debug (SWD)

See the *ARM*® *Cortex*™-*M3 Technical Reference Manual* for more information on the ARM JTAG controller.

5.1 Block Diagram

Figure 5-1. JTAG Module Block Diagram

5.2 Functional Description

A high-level conceptual drawing of the JTAG module is shown in Figure 5-1 on page 46. The JTAG module is composed of the Test Access Port (TAP) controller and serial shift chains with parallel update registers. The TAP controller is a simple state machine controlled by the TRST, TCK and TMS inputs. The current state of the TAP controller depends on the current value of TRST and the sequence of values captured on TMS at the rising edge of TCK. The TAP controller determines when the serial shift chains capture new data, shift data from TDI towards TDO, and update the parallel load registers. The current state of the TAP controller also determines whether the Instruction Register (IR) chain or one of the Data Register (DR) chains is being accessed.

The serial shift chains with parallel load registers are comprised of a single Instruction Register (IR) chain and multiple Data Register (DR) chains. The current instruction loaded in the parallel load register determines which DR chain is captured, shifted, or updated during the sequencing of the TAP controller.

Some instructions, like EXTEST and INTEST, operate on data currently in a DR chain and do not capture, shift, or update any of the chains. Instructions that are not implemented decode to the BYPASS instruction to ensure that the serial path between TDI and TDO is always connected (see Table 5-2 on page 52 for a list of implemented instructions).

See "JTAG and Boundary Scan" on page 491 for JTAG timing diagrams.

5.2.1 JTAG Interface Pins

The JTAG interface consists of five standard pins: TRST, TCK, TMS, TDI, and TDO. These pins and their associated reset state are given in Table 5-1 on page 47. Detailed information on each pin follows.

Table 5-1, JTAG Port Pins Reset State

Pin Name	Data Direction	Internal Pull-Up	Internal Pull-Down	Drive Strength	Drive Value
TRST	Input	Enabled	Disabled	N/A	N/A
TCK	Input	Enabled	Disabled	N/A	N/A
TMS	Input	Enabled	Disabled	N/A	N/A
TDI	Input	Enabled	Disabled	N/A	N/A
TDO	Output	Enabled	Disabled	2-mA driver	High-Z

5.2.1.1 Test Reset Input (TRST)

The $\overline{\mathtt{TRST}}$ pin is an asynchronous active Low input signal for initializing and resetting the JTAG TAP controller and associated JTAG circuitry. When $\overline{\mathtt{TRST}}$ is asserted, the TAP controller resets to the Test-Logic-Reset state and remains there while $\overline{\mathtt{TRST}}$ is asserted. When the TAP controller enters the Test-Logic-Reset state, the JTAG Instruction Register (IR) resets to the default instruction, IDCODE.

By default, the internal pull-up resistor on the TRST pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port B should ensure that the internal pull-up resistor remains enabled on PB7/TRST; otherwise JTAG communication could be lost.

5.2.1.2 Test Clock Input (TCK)

The ${ t TCK}$ pin is the clock for the JTAG module. This clock is provided so the test logic can operate independently of any other system clocks. In addition, it ensures that multiple JTAG TAP controllers that are daisy-chained together can synchronously communicate serial test data between components. During normal operation, ${ t TCK}$ is driven by a free-running clock with a nominal 50% duty cycle. When necessary, ${ t TCK}$ can be stopped at 0 or 1 for extended periods of time. While ${ t TCK}$ is stopped at 0 or 1, the state of the TAP controller does not change and data in the JTAG Instruction and Data Registers is not lost.

By default, the internal pull-up resistor on the ${ t TCK}$ pin is enabled after reset. This assures that no clocking occurs if the pin is not driven from an external source. The internal pull-up and pull-down resistors can be turned off to save internal power as long as the ${ t TCK}$ pin is constantly being driven by an external source.

5.2.1.3 Test Mode Select (TMS)

The TMS pin selects the next state of the JTAG TAP controller. TMS is sampled on the rising edge of TCK. Depending on the current TAP state and the sampled value of TMS, the next state is entered. Because the TMS pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TMS to change on the falling edge of TCK.

Holding TMS high for five consecutive TCK cycles drives the TAP controller state machine to the Test-Logic-Reset state. When the TAP controller enters the Test-Logic-Reset state, the JTAG Instruction Register (IR) resets to the default instruction, IDCODE. Therefore, this sequence can be used as a reset mechanism, similar to asserting TRST. The JTAG Test Access Port state machine can be seen in its entirety in Figure 5-2 on page 49.

By default, the internal pull-up resistor on the TMS pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC1/TMS; otherwise JTAG communication could be lost.

5.2.1.4 Test Data Input (TDI)

The TDI pin provides a stream of serial information to the IR chain and the DR chains. TDI is sampled on the rising edge of TCK and, depending on the current TAP state and the current instruction, presents this data to the proper shift register chain. Because the TDI pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TDI to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDI pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC2/TDI: otherwise JTAG communication could be lost.

5.2.1.5 Test Data Output (TDO)

The TDO pin provides an output stream of serial information from the IR chain or the DR chains. The value of TDO depends on the current TAP state, the current instruction, and the data in the chain being accessed. In order to save power when the JTAG port is not being used, the TDO pin is placed in an inactive drive state when not actively shifting out data. Because TDO can be connected to the TDI of another controller in a daisy-chain configuration, the *IEEE Standard 1149.1* expects the value on TDO to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDO pin is enabled after reset. This assures that the pin remains at a constant logic level when the JTAG port is not being used. The internal pull-up and pull-down resistors can be turned off to save internal power if a High-Z output value is acceptable during certain TAP controller states.

5.2.2 JTAG TAP Controller

The JTAG TAP controller state machine is shown in Figure 5-2 on page 49. The TAP controller state machine is reset to the Test-Logic-Reset state on the assertion of a Power-On-Reset (POR) or the assertion of TRST. Asserting the correct sequence on the TMS pin allows the JTAG module to shift in new instructions, shift in data, or idle during extended testing sequences. For detailed information on the function of the TAP controller and the operations that occur in each state, please refer to *IEEE Standard 1149.1*.

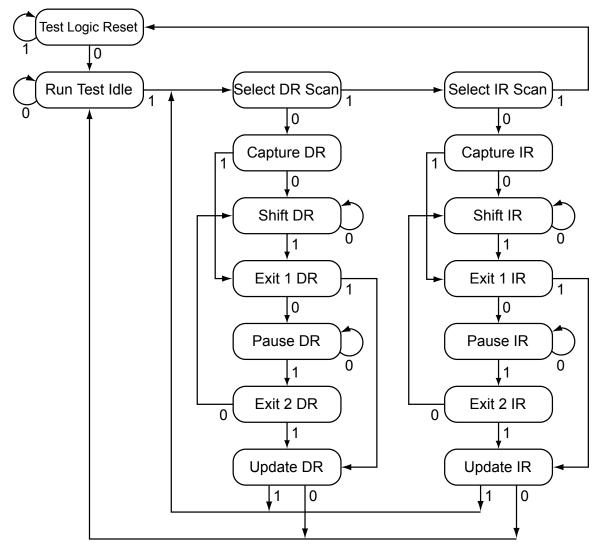

Figure 5-2. Test Access Port State Machine

5.2.3 Shift Registers

The Shift Registers consist of a serial shift register chain and a parallel load register. The serial shift register chain samples specific information during the TAP controller's CAPTURE states and allows this information to be shifted out of TDO during the TAP controller's SHIFT states. While the sampled data is being shifted out of the chain on TDO, new data is being shifted into the serial shift register on TDI. This new data is stored in the parallel load register during the TAP controller's UPDATE states. Each of the shift registers is discussed in detail in "Register Descriptions" on page 52.

5.2.4 Operational Considerations

There are certain operational considerations when using the JTAG module. Because the JTAG pins can be programmed to be GPIOs, board configuration and reset conditions on these pins must be considered. In addition, because the JTAG module has integrated ARM Serial Wire Debug, the method for switching between these two operational modes is described below.

5.2.4.1 GPIO Functionality

When the controller is reset with either a POR or RST, the JTAG/SWD port pins default to their JTAG/SWD configurations. The default configuration includes enabling digital functionality (setting **GPIODEN** to 1), enabling the pull-up resistors (setting **GPIOPUR** to 1), and enabling the alternate hardware function (setting **GPIOAFSEL** to 1) for the PB7 and PC[3:0] JTAG/SWD pins.

It is possible for software to configure these pins as GPIOs after reset by writing 0s to PB7 and PC[3:0] in the **GPIOAFSEL** register. If the user does not require the JTAG/SWD port for debugging or board-level testing, this provides five more GPIOs for use in the design.

Caution – If the JTAG pins are used as GPIOs in a design, PB7 and PC2 cannot have external pull-down resistors connected to both of them at the same time. If both pins are pulled Low during reset, the controller has unpredictable behavior. If this happens, remove one or both of the pull-down resistors, and apply $\overline{\text{RST}}$ or power-cycle the part.

In addition, it is possible to create a software sequence that prevents the debugger from connecting to the Stellaris® microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. This may lock the debugger out of the part. This can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.

The commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 152) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 162) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 163) have been set to 1.

Recovering a "Locked" Device

If software configures any of the JTAG/SWD pins as GPIO and loses the ability to communicate with the debugger, there is a debug sequence that can be used to recover the device. Performing a total of ten JTAG-to-SWD and SWD-to-JTAG switch sequences while holding the device in reset mass erases the flash memory. The sequence to recover the device is:

- Assert and hold the RST signal.
- Perform the JTAG-to-SWD switch sequence.
- Perform the SWD-to-JTAG switch sequence.
- 4. Perform the JTAG-to-SWD switch sequence.
- 5. Perform the SWD-to-JTAG switch sequence.
- Perform the JTAG-to-SWD switch sequence.
- 7. Perform the SWD-to-JTAG switch sequence.
- 8. Perform the JTAG-to-SWD switch sequence.
- 9. Perform the SWD-to-JTAG switch sequence.
- 10. Perform the JTAG-to-SWD switch sequence.
- 11. Perform the SWD-to-JTAG switch sequence.

12. Release the RST signal.

The JTAG-to-SWD and SWD-to-JTAG switch sequences are described in "ARM Serial Wire Debug (SWD)" on page 51. When performing switch sequences for the purpose of recovering the debug capabilities of the device, only steps 1 and 2 of the switch sequence need to be performed.

5.2.4.2 ARM Serial Wire Debug (SWD)

In order to seamlessly integrate the ARM Serial Wire Debug (SWD) functionality, a serial-wire debugger must be able to connect to the Cortex-M3 core without having to perform, or have any knowledge of, JTAG cycles. This is accomplished with a SWD preamble that is issued before the SWD session begins.

The preamble used to enable the SWD interface of the SWJ-DP module starts with the TAP controller in the Test-Logic-Reset state. From here, the preamble sequences the TAP controller through the following states: Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, and Test Logic Reset states.

Stepping through this sequences of the TAP state machine enables the SWD interface and disables the JTAG interface. For more information on this operation and the SWD interface, see the *ARM*® *Cortex*™-*M3 Technical Reference Manual* and the *ARM*® *CoreSight Technical Reference Manual*.

Because this sequence is a valid series of JTAG operations that could be issued, the ARM JTAG TAP controller is not fully compliant to the *IEEE Standard 1149.1*. This is the only instance where the ARM JTAG TAP controller does not meet full compliance with the specification. Due to the low probability of this sequence occurring during normal operation of the TAP controller, it should not affect normal performance of the JTAG interface.

JTAG-to-SWD Switching

To switch the operating mode of the Debug Access Port (DAP) from JTAG to SWD mode, the external debug hardware must send a switch sequence to the device. The 16-bit switch sequence for switching to SWD mode is defined as b1110011110011110, transmitted LSB first. This can also be represented as 16'hE79E when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

- 1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that both JTAG and SWD are in their reset/idle states.
- 2. Send the 16-bit JTAG-to-SWD switch sequence, 16'hE79E.
- Send at least 50 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that if SWJ-DP was already in SWD mode, before sending the switch sequence, the SWD goes into the line reset state.

SWD-to-JTAG Switching

To switch the operating mode of the Debug Access Port (DAP) from SWD to JTAG mode, the external debug hardware must send a switch sequence to the device. The 16-bit switch sequence for switching to JTAG mode is defined as b1110011110011110, transmitted LSB first. This can also be represented as 16'hE73C when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that both JTAG and SWD are in their reset/idle states.

- 2. Send the 16-bit SWD-to-JTAG switch sequence, 16'hE73C.
- 3. Send at least 5 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that if SWJ-DP was already in JTAG mode, before sending the switch sequence, the JTAG goes into the Test Logic Reset state.

5.3 Initialization and Configuration

After a Power-On-Reset or an external reset (RST), the JTAG pins are automatically configured for JTAG communication. No user-defined initialization or configuration is needed. However, if the user application changes these pins to their GPIO function, they must be configured back to their JTAG functionality before JTAG communication can be restored. This is done by enabling the five JTAG pins (PB7 and PC[3:0]) for their alternate function using the **GPIOAFSEL** register.

5.4 Register Descriptions

There are no APB-accessible registers in the JTAG TAP Controller or Shift Register chains. The registers within the JTAG controller are all accessed serially through the TAP Controller. The registers can be broken down into two main categories: Instruction Registers and Data Registers.

5.4.1 Instruction Register (IR)

The JTAG TAP Instruction Register (IR) is a four-bit serial scan chain with a parallel load register connected between the JTAG TDI and TDO pins. When the TAP Controller is placed in the correct states, bits can be shifted into the Instruction Register. Once these bits have been shifted into the chain and updated, they are interpreted as the current instruction. The decode of the Instruction Register bits is shown in Table 5-2 on page 52. A detailed explanation of each instruction, along with its associated Data Register, follows.

IR[3:0]	Instruction	Description
0000	EXTEST	Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction onto the pads.
0001	INTEST	Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction into the controller.
0010	SAMPLE / PRELOAD	Captures the current I/O values and shifts the sampled values out of the Boundary Scan Chain while new preload data is shifted in.
1000	ABORT	Shifts data into the ARM Debug Port Abort Register.
1010	DPACC	Shifts data into and out of the ARM DP Access Register.
1011	APACC	Shifts data into and out of the ARM AC Access Register.
1110	IDCODE	Loads manufacturing information defined by the <i>IEEE Standard 1149.1</i> into the IDCODE chain and shifts it out.
1111	BYPASS	Connects TDI to TDO through a single Shift Register chain.
All Others	Reserved	Defaults to the BYPASS instruction to ensure that TDI is always connected to TDO.

5.4.1.1 EXTEST Instruction

The EXTEST instruction does not have an associated Data Register chain. The EXTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the EXTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the outputs and output enables are used to drive the GPIO pads rather than the signals coming from the core. This allows

tests to be developed that drive known values out of the controller, which can be used to verify connectivity.

5.4.1.2 INTEST Instruction

The INTEST instruction does not have an associated Data Register chain. The INTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the INTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the inputs are used to drive the signals going into the core rather than the signals coming from the GPIO pads. This allows tests to be developed that drive known values into the controller, which can be used for testing. It is important to note that although the RST input pin is on the Boundary Scan Data Register chain, it is only observable.

5.4.1.3 SAMPLE/PRELOAD Instruction

The SAMPLE/PRELOAD instruction connects the Boundary Scan Data Register chain between TDI and TDO. This instruction samples the current state of the pad pins for observation and preloads new test data. Each GPIO pad has an associated input, output, and output enable signal. When the TAP controller enters the Capture DR state during this instruction, the input, output, and output-enable signals to each of the GPIO pads are captured. These samples are serially shifted out of TDO while the TAP controller is in the Shift DR state and can be used for observation or comparison in various tests.

While these samples of the inputs, outputs, and output enables are being shifted out of the Boundary Scan Data Register, new data is being shifted into the Boundary Scan Data Register from TDI. Once the new data has been shifted into the Boundary Scan Data Register, the data is saved in the parallel load registers when the TAP controller enters the Update DR state. This update of the parallel load register preloads data into the Boundary Scan Data Register that is associated with each input, output, and output enable. This preloaded data can be used with the EXTEST and INTEST instructions to drive data into or out of the controller. Please see "Boundary Scan Data Register" on page 55 for more information.

5.4.1.4 ABORT Instruction

The ABORT instruction connects the associated ABORT Data Register chain between TDI and TDO. This instruction provides read and write access to the ABORT Register of the ARM Debug Access Port (DAP). Shifting the proper data into this Data Register clears various error bits or initiates a DAP abort of a previous request. Please see the "ABORT Data Register" on page 55 for more information.

5.4.1.5 DPACC Instruction

The DPACC instruction connects the associated DPACC Data Register chain between TDI and TDO. This instruction provides read and write access to the DPACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to the ARM debug and status registers. Please see "DPACC Data Register" on page 55 for more information.

5.4.1.6 APACC Instruction

The APACC instruction connects the associated APACC Data Register chain between TDI and TDO. This instruction provides read and write access to the APACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to internal components and buses through the Debug Port. Please see "APACC Data Register" on page 55 for more information.

5.4.1.7 IDCODE Instruction

The IDCODE instruction connects the associated IDCODE Data Register chain between <code>TDI</code> and <code>TDO</code>. This instruction provides information on the manufacturer, part number, and version of the ARM core. This information can be used by testing equipment and debuggers to automatically configure their input and output data streams. IDCODE is the default instruction that is loaded into the JTAG Instruction Register when a power-on-reset (POR) is asserted, <code>TRST</code> is asserted, or the Test-Logic-Reset state is entered. Please see "IDCODE Data Register" on page 54 for more information.

5.4.1.8 BYPASS Instruction

The BYPASS instruction connects the associated BYPASS Data Register chain between TDI and TDO. This instruction is used to create a minimum length serial path between the TDI and TDO ports. The BYPASS Data Register is a single-bit shift register. This instruction improves test efficiency by allowing components that are not needed for a specific test to be bypassed in the JTAG scan chain by loading them with the BYPASS instruction. Please see "BYPASS Data Register" on page 54 for more information.

5.4.2 Data Registers

The JTAG module contains six Data Registers. These include: IDCODE, BYPASS, Boundary Scan, APACC, DPACC, and ABORT serial Data Register chains. Each of these Data Registers is discussed in the following sections.

5.4.2.1 IDCODE Data Register

The format for the 32-bit IDCODE Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 5-3 on page 54. The standard requires that every JTAG-compliant device implement either the IDCODE instruction or the BYPASS instruction as the default instruction. The LSB of the IDCODE Data Register is defined to be a 1 to distinguish it from the BYPASS instruction, which has an LSB of 0. This allows auto configuration test tools to determine which instruction is the default instruction.

The major uses of the JTAG port are for manufacturer testing of component assembly, and program development and debug. To facilitate the use of auto-configuration debug tools, the IDCODE instruction outputs a value of 0x3BA00477. This value indicates an ARM Cortex-M3, Version 1 processor. This allows the debuggers to automatically configure themselves to work correctly with the Cortex-M3 during debug.

Figure 5-3. IDCODE Register Format

5.4.2.2 BYPASS Data Register

The format for the 1-bit BYPASS Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 5-4 on page 55. The standard requires that every JTAG-compliant device implement either the BYPASS instruction or the IDCODE instruction as the default instruction. The LSB of the BYPASS Data Register is defined to be a 0 to distinguish it from the IDCODE instruction, which has an LSB of 1. This allows auto configuration test tools to determine which instruction is the default instruction.

Figure 5-4. BYPASS Register Format

5.4.2.3 Boundary Scan Data Register

The format of the Boundary Scan Data Register is shown in Figure 5-5 on page 55. Each GPIO pin, in a counter-clockwise direction from the JTAG port pins, is included in the Boundary Scan Data Register. Each GPIO pin has three associated digital signals that are included in the chain. These signals are input, output, and output enable, and are arranged in that order as can be seen in the figure. In addition to the GPIO pins, the controller reset pin, $\overline{\text{RST}}$, is included in the chain. Because the reset pin is always an input, only the input signal is included in the Data Register chain.

When the Boundary Scan Data Register is accessed with the SAMPLE/PRELOAD instruction, the input, output, and output enable from each digital pad are sampled and then shifted out of the chain to be verified. The sampling of these values occurs on the rising edge of TCK in the Capture DR state of the TAP controller. While the sampled data is being shifted out of the Boundary Scan chain in the Shift DR state of the TAP controller, new data can be preloaded into the chain for use with the EXTEST and INTEST instructions. These instructions either force data out of the controller, with the EXTEST instruction, or into the controller, with the INTEST instruction.

Figure 5-5. Boundary Scan Register Format

For detailed information on the order of the input, output, and output enable bits for each of the GPIO ports, please refer to the Stellaris[®] Family Boundary Scan Description Language (BSDL) files, downloadable from www.luminarymicro.com.

5.4.2.4 APACC Data Register

The format for the 35-bit APACC Data Register defined by ARM is described in the *ARM*® *Cortex*™-*M3 Technical Reference Manual*.

5.4.2.5 DPACC Data Register

The format for the 35-bit DPACC Data Register defined by ARM is described in the *ARM*® *Cortex*™-*M3 Technical Reference Manual*.

5.4.2.6 ABORT Data Register

The format for the 35-bit ABORT Data Register defined by ARM is described in the *ARM*® *Cortex*™-*M3 Technical Reference Manual*.

6 System Control

System control determines the overall operation of the device. It provides information about the device, controls the clocking to the core and individual peripherals, and handles reset detection and reporting.

6.1 Functional Description

The System Control module provides the following capabilities:

- Device identification, see "Device Identification" on page 56
- Local control, such as reset (see "Reset Control" on page 56), power (see "Power Control" on page 59) and clock control (see "Clock Control" on page 59)
- System control (Run, Sleep, and Deep-Sleep modes), see "System Control" on page 61

6.1.1 Device Identification

Seven read-only registers provide software with information on the microcontroller, such as version, part number, SRAM size, flash size, and other features. See the **DID0**, **DID1**, and **DC0-DC4** registers.

6.1.2 Reset Control

This section discusses aspects of hardware functions during reset as well as system software requirements following the reset sequence.

6.1.2.1 CMOD0 and CMOD1 Test-Mode Control Pins

Two pins, CMOD0 and CMOD1, are defined for use by Luminary Micro for testing the devices during manufacture. They have no end-user function and should not be used. The CMOD pins should be connected to ground.

6.1.2.2 Reset Sources

The controller has five sources of reset:

- 1. External reset input pin (RST) assertion, see "RST Pin Assertion" on page 56.
- 2. Power-on reset (POR), see "Power-On Reset (POR)" on page 57.
- 3. Internal brown-out (BOR) detector, see "Brown-Out Reset (BOR)" on page 57.
- 4. Software-initiated reset (with the software reset registers), see "Software Reset" on page 58.
- 5. A watchdog timer reset condition violation, see "Watchdog Timer Reset" on page 58.

After a reset, the **Reset Cause (RESC)** register is set with the reset cause. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an internal POR is the cause, and then all the other bits in the **RESC** register are cleared except for the POR indicator.

6.1.2.3 RST Pin Assertion

The external reset pin (RST) resets the controller. This resets the core and all the peripherals except the JTAG TAP controller (see "JTAG Interface" on page 45). The external reset sequence is as follows:

- 1. The external reset pin (RST) is asserted and then de-asserted.
- 2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution. A few clocks cycles from RST de-assertion to the start of the reset sequence is necessary for synchronization.

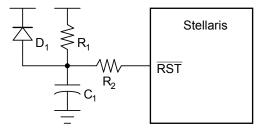

The external reset timing is shown in Figure 21-9 on page 493.

6.1.2.4 Power-On Reset (POR)

The Power-On Reset (POR) circuit monitors the power supply voltage (V_{DD}). The POR circuit generates a reset signal to the internal logic when the power supply ramp reaches a threshold value (V_{TH}). If the application only uses the POR circuit, the $\overline{\tt RST}$ input needs to be connected to the power supply (V_{DD}) through a pull-up resistor (1K to 10K Ω).

The device must be operating within the specified operating parameters at the point when the on-chip power-on reset pulse is complete. The 3.3-V power supply to the device must reach 3.0 V within 10 msec of it crossing 2.0 V to guarantee proper operation. For applications that require the use of an external reset to hold the device in reset longer than the internal POR, the RST input may be used with the circuit as shown in Figure 6-1 on page 57.

Figure 6-1. External Circuitry to Extend Reset

The R_1 and C_1 components define the power-on delay. The R_2 resistor mitigates any leakage from the \overline{RST} input. The diode (D₁) discharges C_1 rapidly when the power supply is turned off.

The Power-On Reset sequence is as follows:

- 1. The controller waits for the later of external reset (RST) or internal POR to go inactive.
- 2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution.

The internal POR is only active on the initial power-up of the controller. The Power-On Reset timing is shown in Figure 21-10 on page 494.

Note: The power-on reset also resets the JTAG controller. An external reset does not.

6.1.2.5 Brown-Out Reset (BOR)

A drop in the input voltage resulting in the assertion of the internal brown-out detector can be used to reset the controller. This is initially disabled and may be enabled by software.

The system provides a brown-out detection circuit that triggers if the power supply (V_{DD}) drops below a brown-out threshold voltage (V_{BTH}) . If a brown-out condition is detected, the system may generate a controller interrupt or a system reset.

Brown-out resets are controlled with the **Power-On and Brown-Out Reset Control (PBORCTL)** register. The BORIOR bit in the **PBORCTL** register must be set for a brown-out condition to trigger a reset.

The brown-out reset is equivelent to an assertion of the external $\overline{\mathtt{RST}}$ input and the reset is held active until the proper V_{DD} level is restored. The **RESC** register can be examined in the reset interrupt handler to determine if a Brown-Out condition was the cause of the reset, thus allowing software to determine what actions are required to recover.

The internal Brown-Out Reset timing is shown in Figure 21-11 on page 494.

6.1.2.6 Software Reset

Software can reset a specific peripheral or generate a reset to the entire system .

Peripherals can be individually reset by software via three registers that control reset signals to each peripheral (see the **SRCRn** registers). If the bit position corresponding to a peripheral is set and subsequently cleared, the peripheral is reset. The encoding of the reset registers is consistent with the encoding of the clock gating control for peripherals and on-chip functions (see "System Control" on page 61). Note that all reset signals for all clocks of the specified unit are asserted as a result of a software-initiated reset.

The entire system can be reset by software by setting the SYSRESETREQ bit in the Cortex-M3 Application Interrupt and Reset Control register resets the entire system including the core. The software-initiated system reset sequence is as follows:

- 1. A software system reset is initiated by writing the SYSRESETREQ bit in the ARM Cortex-M3 Application Interrupt and Reset Control register.
- An internal reset is asserted.
- The internal reset is deasserted and the controller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The software-initiated system reset timing is shown in Figure 21-12 on page 494.

6.1.2.7 Watchdog Timer Reset

The watchdog timer module's function is to prevent system hangs. The watchdog timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out.

After the first time-out event, the 32-bit counter is reloaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled, the watchdog timer asserts its reset signal to the system. The watchdog timer reset sequence is as follows:

- 1. The watchdog timer times out for the second time without being serviced.
- 2. An internal reset is asserted.
- The internal reset is released and the controller loads from memory the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution.

The watchdog reset timing is shown in Figure 21-13 on page 494.

6.1.3 Power Control

The Stellaris microcontroller provides an integrated LDO regulator that may be used to provide power to the majority of the controller's internal logic. The LDO regulator provides software a mechanism to adjust the regulated value, in small increments (VSTEP), over the range of 2.25 V to 2.75 V (inclusive)—or 2.5 V \pm 10%. The adjustment is made by changing the value of the VADJ field in the **LDO Power Control (LDOPCTL)** register.

Note: The use of the LDO is optional. The internal logic may be supplied by the on-chip LDO or by an external regulator. If the LDO is used, the LDO output pin is connected to the VDD25 pins on the printed circuit board. The LDO requires decoupling capacitors on the printed circuit board. If an external regulator is used, it is strongly recommended that the external regulator supply the controller only and not be shared with other devices on the printed circuit board.

6.1.4 Clock Control

System control determines the control of clocks in this part.

6.1.4.1 Fundamental Clock Sources

There are four clock sources for use in the device:

- Internal Oscillator (IOSC): The internal oscillator is an on-chip clock source. It does not require the use of any external components. The frequency of the internal oscillator is 12 MHz ± 30%. Applications that do not depend on accurate clock sources may use this clock source to reduce system cost. The internal oscillator is the clock source the device uses during and following POR. If the main oscillator is required, software must enable the main oscillator following reset and allow the main oscillator to stabilize before changing the clock reference.
- Main Oscillator: The main oscillator provides a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the OSC0 input pin, or an external crystal is connected across the OSC0 input and OSC1 output pins. The crystal value allowed depends on whether the main oscillator is used as the clock reference source to the PLL. If so, the crystal must be one of the supported frequencies between 3.579545 MHz through 8.192 MHz (inclusive). If the PLL is not being used, the crystal may be any one of the supported frequencies between 1 MHz and 8.192 MHz. The single-ended clock source range is from DC through the specified speed of the device. The supported crystals are listed in the XTAL bit in the RCC register (see page 72).
- Internal 30-kHz Oscillator: The internal 30-kHz oscillator is similar to the internal oscillator, except that it provides an operational frequency of 30 kHz ± 30%. It is intended for use during Deep-Sleep power-saving modes. This power-savings mode benefits from reduced internal switching and also allows the main oscillator to be powered down.

The internal system clock (sysclk), is derived from any of the four sources plus two others: the output of the internal PLL, and the internal oscillator divided by four (3 MHz \pm 30%). The frequency of the PLL clock reference must be in the range of 3.579545 MHz to 8.192 MHz (inclusive).

The Run-Mode Clock Configuration (RCC) and Run-Mode Clock Configuration 2 (RCC2) registers provide control for the system clock. The RCC2 register is provided to extend fields that offer additional encodings over the RCC register. When used, the RCC2 register field values are

used by the logic over the corresponding field in the **RCC** register. In particular, **RCC2** provides for a larger assortment of clock configuration options.

6.1.4.2 Crystal Configuration for the Main Oscillator (MOSC)

The main oscillator supports the use of a select number of crystals. If the main oscillator is used by the PLL as a reference clock, the supported range of crystals is 3.579545 to 8.192 MHz, otherwise, the range of supported crystals is 1 to 8.192 MHz.

The XTAL bit in the **RCC** register (see page 72) describes the available crystal choices and default programming values.

Software configures the **RCC** register XTAL field with the crystal number. If the PLL is used in the design, the XTAL field value is internally translated to the PLL settings.

6.1.4.3 PLL Frequency Configuration

The PLL is disabled by default during power-on reset and is enabled later by software if required. Software configures the PLL input reference clock source, specifies the output divisor to set the system clock frequency, and enables the PLL to drive the output.

If the main oscillator provides the clock reference to the PLL, the translation provided by hardware and used to program the PLL is available for software in the **XTAL to PLL Translation (PLLCFG)** register (see page 76). The internal translation provides a translation within \pm 1% of the targeted PLL VCO frequency.

The Crystal Value field (XTAL) on page 72 describes the available crystal choices and default programming of the **PLLCFG** register. The crystal number is written into the XTAL field of the **Run-Mode Clock Configuration (RCC)** register. Any time the XTAL field changes, the new settings are translated and the internal PLL settings are updated.

6.1.4.4 PLL Modes

The PLL has two modes of operation: Normal and Power-Down

- Normal: The PLL multiplies the input clock reference and drives the output.
- Power-Down: Most of the PLL internal circuitry is disabled and the PLL does not drive the output.

The modes are programmed using the RCC/RCC2 register fields (see page 72 and page 77).

6.1.4.5 PLL Operation

If the PLL configuration is changed, the PLL output frequency is unstable until it reconverges (relocks) to the new setting. The time between the configuration change and relock is T_{READY} (see Table 21-6 on page 487). During this time, the PLL is not usable as a clock reference.

The PLL is changed by one of the following:

- Change to the XTAL value in the RCC register—writes of the same value do not cause a relock.
- Change in the PLL from Power-Down to Normal mode.

A counter is defined to measure the T_{READY} requirement. The counter is clocked by the main oscillator. The range of the main oscillator has been taken into account and the down counter is set to 0x1200 (that is, ~600 μ s at an 8.192 MHz external oscillator clock). Hardware is provided to keep the PLL from being used as a system clock until the T_{READY} condition is met after one of the

two changes above. It is the user's responsibility to have a stable clock source (like the main oscillator) before the **RCC/RCC2** register is switched to use the PLL.

6.1.5 System Control

For power-savings purposes, the **RCGCn**, **SCGCn**, and **DCGCn** registers control the clock gating logic for each peripheral or block in the system while the controller is in Run, Sleep, and Deep-Sleep mode, respectively.

In Run mode, the processor executes code. In Sleep mode, the clock frequency of the active peripherals is unchanged, but the processor is not clocked and therefore no longer executes code. In Deep-Sleep mode, the clock frequency of the active peripherals may change (depending on the Run mode clock configuration) in addition to the processor clock being stopped. An interrupt returns the device to Run mode from one of the sleep modes; the sleep modes are entered on request from the code. Each mode is described in more detail below.

There are four levels of operation for the device defined as:

- Run Mode. Run mode provides normal operation of the processor and all of the peripherals that are currently enabled by the RCGCn registers. The system clock can be any of the available clock sources including the PLL.
- Sleep Mode. Sleep mode is entered by the Cortex-M3 core executing a WFI (Wait for Interrupt) instruction. Any properly configured interrupt event in the system will bring the processor back into Run mode. See the system control NVIC section of the ARM® Cortex™-M3 Technical Reference Manual for more details.
 - In Sleep mode, the Cortex-M3 processor core and the memory subsystem are not clocked. Peripherals are clocked that are enabled in the **SCGCn** register when auto-clock gating is enabled (see the **RCC** register) or the **RCGCn** register when the auto-clock gating is disabled. The system clock has the same source and frequency as that during Run mode.
- Deep-Sleep Mode. Deep-Sleep mode is entered by first writing the Deep Sleep Enable bit in the ARM Cortex-M3 NVIC system control register and then executing a WFI instruction. Any properly configured interrupt event in the system will bring the processor back into Run mode. See the system control NVIC section of the ARM® Cortex™-M3 Technical Reference Manual for more details.

The Cortex-M3 processor core and the memory subsystem are not clocked. Peripherals are clocked that are enabled in the **DCGCn** register when auto-clock gating is enabled (see the **RCC** register) or the **RCGCn** register when auto-clock gating is disabled. The system clock source is the main oscillator by default or the internal oscillator specified in the **DSLPCLKCFG** register if one is enabled. When the **DSLPCLKCFG** register is used, the internal oscillator is powered up, if necessary, and the main oscillator is powered down. If the PLL is running at the time of the WFI instruction, hardware will power the PLL down and override the SYSDIV field of the active **RCC/RCC2** register to be /16 or /64, respectively. When the Deep-Sleep exit event occurs, hardware brings the system clock back to the source and frequency it had at the onset of Deep-Sleep mode before enabling the clocks that had been stopped during the Deep-Sleep duration.

6.2 Initialization and Configuration

The PLL is configured using direct register writes to the RCC/RCC2 register. If the RCC2 register is being used, the USERCC2 bit must be set and the appropriate RCC2 bit/field is used. The steps required to successfully change the PLL-based system clock are:

- 1. Bypass the PLL and system clock divider by setting the BYPASS bit and clearing the USESYS bit in the RCC register. This configures the system to run off a "raw" clock source (using the main oscillator or internal oscillator) and allows for the new PLL configuration to be validated before switching the system clock to the PLL.
- 2. Select the crystal value (XTAL) and oscillator source (OSCSRC), and clear the PWRDN bit in RCC/RCC2. Setting the XTAL field automatically pulls valid PLL configuration data for the appropriate crystal, and clearing the PWRDN bit powers and enables the PLL and its output.
- 3. Select the desired system divider (SYSDIV) in RCC/RCC2 and set the USESYS bit in RCC. The SYSDIV field determines the system frequency for the microcontroller.
- Wait for the PLL to lock by polling the PLLLRIS bit in the Raw Interrupt Status (RIS) register.
- 5. Enable use of the PLL by clearing the BYPASS bit in RCC/RCC2.

6.3 Register Map

Table 6-1 on page 62 lists the System Control registers, grouped by function. The offset listed is a hexadecimal increment to the register's address, relative to the System Control base address of 0x400F.E000.

Note: Spaces in the System Control register space that are not used are reserved for future or internal use by Luminary Micro, Inc. Software should not modify any reserved memory address.

6.4 Register Descriptions

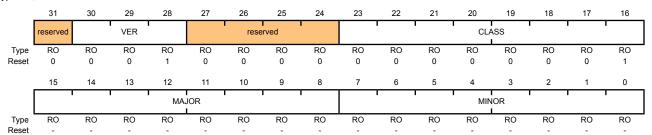

All addresses given are relative to the System Control base address of 0x400F.E000.

Register 1: Device Identification 0 (DID0), offset 0x000

This register identifies the version of the device.

Device Identification 0 (DID0)

Base 0x400F.E000 Offset 0x000 Type RO, reset -

Bit/Field	Name	Туре	Reset	Description
31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
30:28	VER	RO	0x1	DID0 Version
				This field defines the $\textbf{DID0}$ register format version. The version number is numeric. The value of the \mathtt{VER} field is encoded as follows:
				Value Description
				0x1 First revision of the DID0 register format, for Stellaris® Fury-class devices .
27:24	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:16	CLASS	RO	0x1	Device Class

The CLASS field value identifies the internal design from which all mask sets are generated for all devices in a particular product line. The CLASS field value is changed for new product lines, for changes in fab process (for example, a remap or shrink), or any case where the MAJOR or MINOR fields require differentiation from prior devices. The value of the CLASS field is encoded as follows (all other encodings are reserved):

Value Description

0x0 Stellaris® Sandstorm-class devices.

0x1 Stellaris® Fury-class devices.

Bit/Field	Name	Туре	Reset	Description
15:8	MAJOR	RO	-	Major Revision
				This field specifies the major revision number of the device. The major revision reflects changes to base layers of the design. The major revision number is indicated in the part number as a letter (A for first revision, B for second, and so on). This field is encoded as follows:
				Value Description
				0x0 Revision A (initial device)
				0x1 Revision B (first base layer revision)
				0x2 Revision C (second base layer revision)
				and so on.
7:0	MINOR	RO	-	Minor Revision
				This field specifies the minor revision number of the device. The minor revision reflects changes to the metal layers of the design. The ${\tt MINOR}$ field value is reset when the ${\tt MAJOR}$ field is changed. This field is numeric and is encoded as follows:
				Value Description
				0x0 Initial device, or a major revision update.
				0x1 First metal layer change.
				0x2 Second metal layer change.
				and so on.

November 30, 2007 65

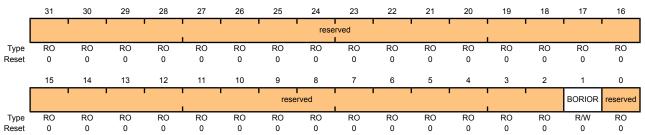

Register 2: Brown-Out Reset Control (PBORCTL), offset 0x030

This register is responsible for controlling reset conditions after initial power-on reset.

Brown-Out Reset Control (PBORCTL)

Base 0x400F.E000

Offset 0x030 Type R/W, reset 0x0000.7FFD

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORIOR	R/W	0	BOR Interrupt or Reset
				This bit controls how a BOR event is signaled to the controller. If set, a reset is signaled. Otherwise, an interrupt is signaled.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

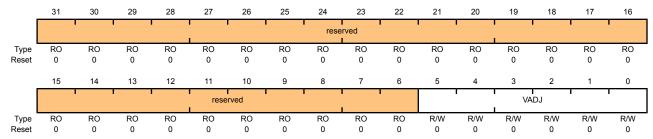

Register 3: LDO Power Control (LDOPCTL), offset 0x034

The VADJ field in this register adjusts the on-chip output voltage (V_{OUT}).

LDO Power Control (LDOPCTL)

Base 0x400F.E000 Offset 0x034

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:0	VADJ	R/W	0x0	LDO Output Voltage

This field sets the on-chip output voltage. The programming values for the \mathtt{VADJ} field are provided below.

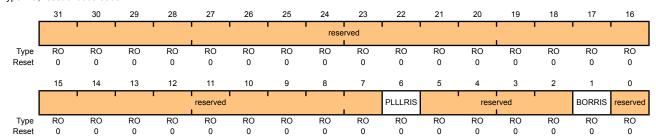

Value	$V_{OUT}(V)$
0x00	2.50
0x01	2.45
0x02	2.40
0x03	2.35
0x04	2.30
0x05	2.25
0x06-0x3F	Reserved
0x1B	2.75
0x1C	2.70
0x1D	2.65
0x1E	2.60
0x1F	2.55

Register 4: Raw Interrupt Status (RIS), offset 0x050

Central location for system control raw interrupts. These are set and cleared by hardware.

Raw Interrupt Status (RIS)

Base 0x400F.E000 Offset 0x050 Type RO, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	PLLLRIS	RO	0	PLL Lock Raw Interrupt Status
				This bit is set when the PLL $\mathrm{T}_{\mathrm{READY}}$ Timer asserts.
5:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORRIS	RO	0	Brown-Out Reset Raw Interrupt Status
				This bit is the raw interrupt status for any brown-out conditions. If set, a brown-out condition is currently active. This is an unregistered signal from the brown-out detection circuit. An interrupt is reported if the BORIM bit in the IMC register is set and the BORIOR bit in the PBORCTL register is cleared.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

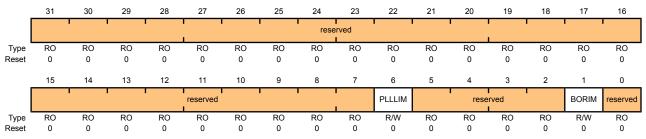

Register 5: Interrupt Mask Control (IMC), offset 0x054

Central location for system control interrupt masks.

Interrupt Mask Control (IMC)

Base 0x400F.E000

Offset 0x054 Type R/W, reset 0x0000.0000

D://E: 11		-	Б.,	
Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	PLLLIM	R/W	0	PLL Lock Interrupt Mask
				This bit specifies whether a current limit detection is promoted to a controller interrupt. If set, an interrupt is generated if PLLLRIS in RIS is set; otherwise, an interrupt is not generated.
5:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORIM	R/W	0	Brown-Out Reset Interrupt Mask
				This bit specifies whether a brown-out condition is promoted to a controller interrupt. If set, an interrupt is generated if BORRIS is set; otherwise, an interrupt is not generated.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

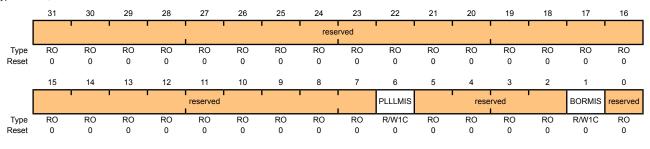

Register 6: Masked Interrupt Status and Clear (MISC), offset 0x058

Central location for system control result of RIS AND IMC to generate an interrupt to the controller. All of the bits are R/W1C and this action also clears the corresponding raw interrupt bit in the RIS register (see page 68).

Masked Interrupt Status and Clear (MISC)

Base 0x400F.E000

Offset 0x058
Type R/W1C, reset 0x0000.0000

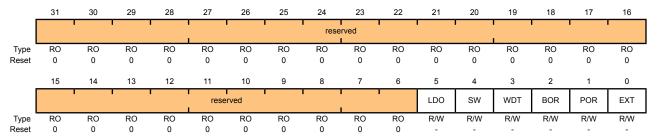

Bit/Field	Name	Туре	Reset	Description
31:7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	PLLLMIS	R/W1C	0	PLL Lock Masked Interrupt Status
				This bit is set when the PLL T_{READY} timer asserts. The interrupt is cleared by writing a 1 to this bit.
5:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORMIS	R/W1C	0	BOR Masked Interrupt Status
				The ${\tt BORMIS}$ is simply the ${\tt BORRIS}$ ANDed with the mask value, ${\tt BORIM}.$
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 7: Reset Cause (RESC), offset 0x05C

This register is set with the reset cause after reset. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an external reset is the cause, and then all the other bits in the **RESC** register are cleared.

Reset Cause (RESC)

Base 0x400F.E000 Offset 0x05C Type R/W, reset -

Bit/Field	Name	Туре	Reset	Description
31:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	LDO	R/W	-	LDO Reset
				When set, indicates the LDO circuit has lost regulation and has generated a reset event.
4	SW	R/W	-	Software Reset
				When set, indicates a software reset is the cause of the reset event.
3	WDT	R/W	-	Watchdog Timer Reset
				When set, indicates a watchdog reset is the cause of the reset event.
2	BOR	R/W	-	Brown-Out Reset
				When set, indicates a brown-out reset is the cause of the reset event.
1	POR	R/W	-	Power-On Reset
				When set, indicates a power-on reset is the cause of the reset event.
0	EXT	R/W	-	External Reset
				When set, indicates an external reset ($\overline{\mbox{\scriptsize RST}}$ assertion) is the cause of

the reset event.

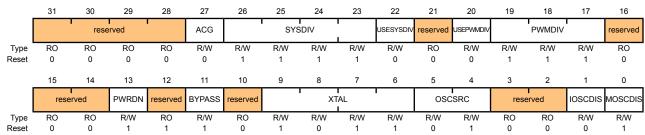

Register 8: Run-Mode Clock Configuration (RCC), offset 0x060

This register is defined to provide source control and frequency speed.

Run-Mode Clock Configuration (RCC)

Base 0x400F.E000 Offset 0x060

Type R/W, reset 0x07AE.3AD1

Bit/Field	Name	Type	Reset	Description
31:28	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

27 ACG R/W 0 Auto Clock Gating

This bit specifies whether the system uses the Sleep-Mode Clock Gating Control (SCGCn) registers and Deep-Sleep-Mode Clock Gating Control (DCGCn) registers if the controller enters a Sleep or Deep-Sleep mode (respectively). If set, the SCGCn or DCGCn registers are used to control the clocks distributed to the peripherals when the controller is in a sleep mode. Otherwise, the Run-Mode Clock Gating Control (RCGCn) registers are used when the controller enters a sleep mode.

The **RCGCn** registers are always used to control the clocks in Run mode.

This allows peripherals to consume less power when the controller is in a sleep mode and the peripheral is unused.

Bit/Field	Name	Туре	Reset	Description						
26:23	SYSDIV	R/W	0xF	System Clock Diviso	r					
				Specifies which divisor is used to generate the system clock fro PLL output.						
				The PLL VCO freque	ency is 400 MHz.					
				Value Divisor (RVP)	ASS=1) Frequency (BYPASS=0)					
				0x0 reserved	reserved

				0x7 /8	25 MHz					
				0x8 /9	22.22 MHz					
				0x9 /10	20 MHz					
				0xA /11	18.18 MHz					
				0xB /12	16.67 MHz					
				0xC /13	15.38 MHz					
				0xD /14	14.29 MHz					
				0xE /15	13.33 MHz					
				0xF /16	12.5 MHz (default)					
				page 72), the SYSDI	n-Mode Clock Configuration (RCC) register (see V value is MINSYSDIV if a lower divider was LL is being used. This lower value is allowed to urce.					
22	USESYSDIV	R/W	0	Enable System Cloc	k Divider					
				Use the system clock divider as the source for the system clock. The system clock divider is forced to be used when the PLL is selected a the source.						
21	reserved	RO	0	compatibility with futi	rely on the value of a reserved bit. To provide ure products, the value of a reserved bit should be ead-modify-write operation.					
20	USEPWMDIV	R/W	0	Enable PWM Clock I	Divisor					
				Use the PWM clock	divider as the source for the PWM clock.					

November 30, 2007 73

Bit/Field	Name	Type	Reset	Description
19:17	PWMDIV	R/W	0x7	PWM Unit Clock Divisor
				This field specifies the binary divisor used to predivide the system clock down for use as the timing reference for the PWM module. This clock is only power 2 divide and rising edge is synchronous without phase shift from the system clock.
				Value Divisor
				0x0 /2
				0x1 /4
				0x2 /8
				0x3 /16
				0x4 /32
				0x5 /64
				0x6 /64
				0x7 /64 (default)
16:14	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13	PWRDN	R/W	1	PLL Power Down
				This bit connects to the PLL PWRDN input. The reset value of 1 powers down the PLL.
12	reserved	RO	1	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	BYPASS	R/W	1	PLL Bypass
				Chooses whether the system clock is derived from the PLL output or the OSC source. If set, the clock that drives the system is the OSC source. Otherwise, the clock that drives the system is the PLL output clock divided by the system divider.
				Note: The ADC must be clocked from the PLL or directly from a 14-MHz to 18-MHz clock source to operate properly. While the ADC works in a 14-18 MHz range, to maintain a 1 M sample/second rate, the ADC must be provided a 16-MHz clock source.
10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

					(

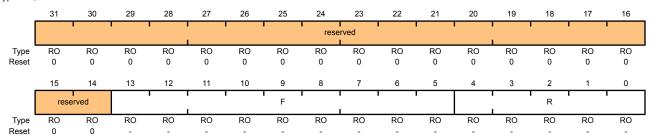

Register 9: XTAL to PLL Translation (PLLCFG), offset 0x064

This register provides a means of translating external crystal frequencies into the appropriate PLL settings. This register is initialized during the reset sequence and updated anytime that the XTAL field changes in the **Run-Mode Clock Configuration (RCC)** register (see page 72).

The PLL frequency is calculated using the PLLCFG field values, as follows:

XTAL to PLL Translation (PLLCFG)

Base 0x400F.E000 Offset 0x064 Type RO, reset -

Bit/Field	Name	Туре	Reset	Description
31:14	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13:5	F	RO	-	PLL F Value This field specifies the value supplied to the PLL's F input.
4:0	R	RO	-	PLL R Value

This field specifies the value supplied to the PLL's R input.

16

Register 10: Run-Mode Clock Configuration 2 (RCC2), offset 0x070

This register overrides the **RCC** equivalent register fields when the <code>USERCC2</code> bit is set. This allows <code>RCC2</code> to be used to extend the capabilities, while also providing a means to be backward-compatible to previous parts. The fields within the **RCC2** register occupy the same bit positions as they do within the **RCC** register as LSB-justified.

The SYSDIV2 field is wider so that additional larger divisors are possible. This allows a lower system clock frequency for improved Deep Sleep power consumption.

Type RO, reset 0x007F.002F

Bit/Field	Name	Type	Reset	Description
31:16	SRAMSZ	RO	0x007F	SRAM Size

Indicates the size of the on-chip SRAM memory.

Description 0x007F 32 KB of SRAM

15:0 **FLASHSZ** RO 0x002F Flash Size

Indicates the size of the on-chip flash memory.

Value Description 0x002F 96 KB of Flash

Register 14: Device Capabilities 1 (DC1), offset 0x010

This register provides a list of features available in the system. The Stellaris family uses this register format to indicate the availability of the following family features in the specific device: CANs, PWM, ADC, Watchdog timer, Hibernation module, and debug capabilities. This register also indicates the maximum clock frequency and maximum ADC sample rate. The format of this register is consistent with the RCGC0, SCGC0, and DCGC0 clock control registers and the SRCR0 software reset control register.

				When set, indicates that the PWM pin 0 is present.

Register 17: Device Capabilities 4 (DC4), offset 0x01C

This register provides a list of features available in the system. The Stellaris family uses this register format to indicate the availability of the following family features in the specific device: Ethernet MAC and PHY, GPIOs, and CCP I/Os. The format of this register is consistent with the RCGC2, SCGC2, and DCGC2 clock control registers and the SRCR2 software reset control register.

Device Capabilities 4 (DC4)

Base 0x400F.E000 Offset 0x01C

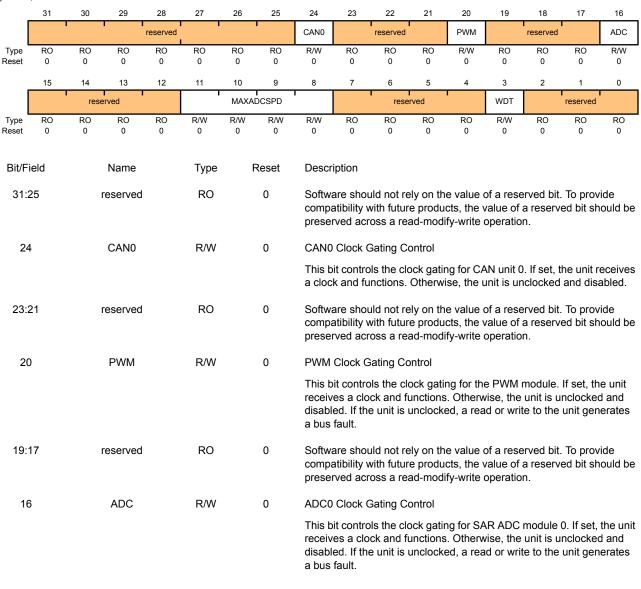

Register 18: Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Run Mode Clock Gating Control Register 0 (RCGC0)

Base 0x400F.E000 Offset 0x100

Type R/W, reset 0x00000040

Bit/Field	Name	Туре	Reset	Description
15:12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:8	MAXADCSPD	R/W	0	ADC Sample Speed
				This field sets the rate at which the ADC samples data. You cannot set the rate higher than the maximum rate. You can set the sample rate by setting the MAXADCSPD bit as follows:
				Value Description
				0x1 250K samples/second
				0x0 125K samples/second
7:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	WDT	R/W	0	WDT Clock Gating Control
				This bit controls the clock gating for the WDT module. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, a read or write to the unit generates a bus fault.
2:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 19: Sleep Mode Clock Gating Control Register 0 (SCGC0), offset 0x110

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

15:13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	R/W	0	I2C0 Clock Gating Control
				This bit controls the clock gating for I2C module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
11:5	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	SSI0	R/W	0	SSI0 Clock Gating Control
				This bit controls the clock gating for SSI module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
3:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	UART1	R/W	0	UART1 Clock Gating Control
				This bit controls the clock gating for UART module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
0	UART0	R/W	0	UART0 Clock Gating Control
				This bit controls the clock gating for UART module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

November 30, 2007 97

Register 22: Sleep Mode Clock Gating Control Register 1 (SCGC1), offset 0x114

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the ACG bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Bit/Field	Name	Туре	Reset	Description
17	TIMER1	R/W	0	Timer 1 Clock Gating Control
				This bit controls the clock gating for General-Purpose Timer module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
16	TIMER0	R/W	0	Timer 0 Clock Gating Control
				This bit controls the clock gating for General-Purpose Timer module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
15:13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	R/W	0	I2C0 Clock Gating Control
				This bit controls the clock gating for I2C module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
11:5	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	SSI0	R/W	0	SSI0 Clock Gating Control
				This bit controls the clock gating for SSI module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
3:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	UART1	R/W	0	UART1 Clock Gating Control
				This bit controls the clock gating for UART module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.
0	UART0	R/W	0	UART0 Clock Gating Control
				This bit controls the clock gating for UART module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled. If the unit is unclocked, reads or writes to the unit will generate a bus fault.

Register 24: Run Mode Clock Gating Control Register 2 (RCGC2), offset 0x108

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. RCGC2 is the clock configuration register for running operation, SCGC2 for Sleep operation, and DCGC2 for Deep-Sleep operation. Setting the ACG bit in the Run-Mode Clock Configuration (RCC) register specifies that the system uses sleep modes.

7 Internal Memory

The LM3S2432 microcontroller comes with 32 KB of bit-banded SRAM and 96 KB of flash memory. The flash controller provides a user-friendly interface, making flash programming a simple task. Flash protection can be applied to the flash memory on a 2-KB block basis.

7.1 Block Diagram

Figure 7-1. Flash Block Diagram

7.2 Functional Description

This section describes the functionality of both the flash and SRAM memories.

7.2.1 SRAM Memory

The internal SRAM of the Stellaris[®] devices is located at address 0x2000.0000 of the device memory map. To reduce the number of time consuming read-modify-write (RMW) operations, ARM has introduced *bit-banding* technology in the Cortex-M3 processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

The bit-band alias is calculated by using the formula:

```
bit-band alias = bit-band base + (byte offset * 32) + (bit number * 4)
```

For example, if bit 3 at address 0x2000.1000 is to be modified, the bit-band alias is calculated as:

```
0x2200.0000 + (0x1000 * 32) + (3 * 4) = 0x2202.000C
```

With the alias address calculated, an instruction performing a read/write to address 0x2202.000C allows direct access to only bit 3 of the byte at address 0x2000.1000.

For details about bit-banding, please refer to Chapter 4, "Memory Map" in the *ARM*® *Cortex*™-*M3 Technical Reference Manual.*

7.2.2 Flash Memory

The flash is organized as a set of 1-KB blocks that can be individually erased. Erasing a block causes the entire contents of the block to be reset to all 1s. An individual 32-bit word can be programmed to change bits that are currently 1 to a 0. These blocks are paired into a set of 2-KB blocks that can be individually protected. The protection allows blocks to be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

See also "Serial Flash Loader" on page 497 for a preprogrammed flash-resident utility used to download code to the flash memory of a device without the use of a debug interface.

7.2.2.1 Flash Memory Timing

The timing for the flash is automatically handled by the flash controller. However, in order to do so, it must know the clock rate of the system in order to time its internal signals properly. The number of clock cycles per microsecond must be provided to the flash controller for it to accomplish this timing. It is software's responsibility to keep the flash controller updated with this information via the **USec Reload (USECRL)** register.

On reset, the **USECRL** register is loaded with a value that configures the flash timing so that it works with the maximum clock rate of the part. If software changes the system operating frequency, the new operating frequency minus 1 (in MHz) must be loaded into **USECRL** before any flash modifications are attempted. For example, if the device is operating at a speed of 20 MHz, a value of 0x13 (20-1) must be written to the **USECRL** register.

7.2.2.2 Flash Memory Protection

The user is provided two forms of flash protection per 2-KB flash blocks in two pairs of 32-bit wide registers. The protection policy for each form is controlled by individual bits (per policy per block) in the **FMPPEn** and **FMPREn** registers.

- Flash Memory Protection Program Enable (FMPPEn): If set, the block may be programmed (written) or erased. If cleared, the block may not be changed.
- Flash Memory Protection Read Enable (FMPREn): If set, the block may be executed or read by software or debuggers. If cleared, the block may only be executed. The contents of the memory block are prohibited from being accessed as data and traversing the DCode bus.

The policies may be combined as shown in Table 7-1 on page 114.

Table 7-1. Flash Protection Policy Combinations

FMPPE n	FMPREn	Protection
0		Execute-only protection. The block may only be executed and may not be written or erased. This mode is used to protect code.
1	0	The block may be written, erased or executed, but not read. This combination is unlikely to be used.
0		Read-only protection. The block may be read or executed but may not be written or erased. This mode is used to lock the block from further modification while allowing any read or execute access.
1	1	No protection. The block may be written, erased, executed or read.

An access that attempts to program or erase a PE-protected block is prohibited. A controller interrupt may be optionally generated (by setting the AMASK bit in the **FIM** register) to alert software developers of poorly behaving software during the development and debug phases.

An access that attempts to read an RE-protected block is prohibited. Such accesses return data filled with all 0s. A controller interrupt may be optionally generated to alert software developers of poorly behaving software during the development and debug phases.

The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This implements a policy of open access and programmability. The register bits may be changed by writing the specific register bit. The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. Details on programming these bits are discussed in "Nonvolatile Register Programming" on page 115.

7.3 Flash Memory Initialization and Configuration

7.3.1 Flash Programming

The Stellaris[®] devices provide a user-friendly interface for flash programming. All erase/program operations are handled via three registers: **FMA**, **FMD**, and **FMC**.

7.3.1.1 To program a 32-bit word

- Write source data to the FMD register.
- 2. Write the target address to the **FMA** register.
- Write the flash write key and the WRITE bit (a value of 0xA442.0001) to the FMC register.
- 4. Poll the **FMC** register until the WRITE bit is cleared.

7.3.1.2 To perform an erase of a 1-KB page

- 1. Write the page address to the **FMA** register.
- 2. Write the flash write key and the ERASE bit (a value of 0xA442.0002) to the FMC register.
- 3. Poll the FMC register until the ERASE bit is cleared.

7.3.1.3 To perform a mass erase of the flash

- 1. Write the flash write key and the MERASE bit (a value of 0xA442.0004) to the FMC register.
- 2. Poll the FMC register until the MERASE bit is cleared.

7.3.2 Nonvolatile Register Programming

This section discusses how to update registers that are resident within the flash memory itself. These registers exist in a separate space from the main flash array and are not affected by an ERASE or MASS ERASE operation. These nonvolatile registers are updated by using the COMT bit in the **FMC** register to activate a write operation. For the **USER_DBG** register, the data to be written must be loaded into the **FMD** register before it is "committed". All other registers are R/W and can have their operation tried before committing them to nonvolatile memory.

Important: These registers can only have bits changed from 1 to 0 by the user and there is no mechanism for the user to erase them back to a 1 value.

In addition, the **USER_REG0**, **USER_REG1**, and **USER_DBG** use bit 31 (NW) of their respective registers to indicate that they are available for user write. These three registers can only be written once whereas the flash protection registers may be written multiple times. Table 7-2 on page 115 provides the FMA address required for commitment of each of the registers and the source of the data to be written when the COMT bit of the **FMC** register is written with a value of 0xA442.0008. After writing the COMT bit, the user may poll the **FMC** register to wait for the commit operation to complete.

Table 7-2. Flash Resident Registers^a

Register to be Committed	FMA Value	Data Source
FMPRE0	0x0000.0000	FMPRE0
FMPRE1	0x0000.0002	FMPRE1
FMPRE2	0x0000.0004	FMPRE2
FMPRE3	0x0000.0008	FMPRE3
FMPPE0	0x0000.0001	FMPPE0
FMPPE1	0x0000.0003	FMPPE1
FMPPE2	0x0000.0005	FMPPE2
FMPPE3	0x0000.0007	FMPPE3
USER_REG0	0x8000.0000	USER_REG0
USER_REG1	0x8000.0001	USER_REG1
USER_DBG	0x7510.0000	FMD

a. Which FMPREn and FMPPEn registers are available depend on the flash size of your particular Stellaris® device.

7.4 Register Map

Table 7-3 on page 115 lists the Flash memory and control registers. The offset listed is a hexadecimal increment to the register's address. The **FMA**, **FMD**, **FMC**, **FCRIS**, **FCIM**, and **FCMISC** registers are relative to the Flash control base address of 0x400F.D000. The **FMPREn**, **FMPPEn**, **USECRL**, **USER_DBG**, and **USER_REGn** registers are relative to the System Control base address of 0x400F.E000.

7.5 Flash Register Descriptions (Flash Control Offset)

The remainder of this section lists and describes the Flash Memory registers, in numerical order by address offset. Registers in this section are relative to the Flash control base address of 0x400F.D000.

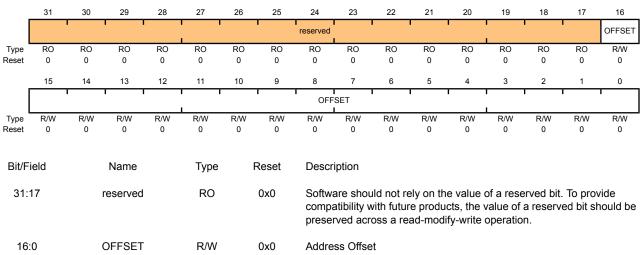

Register 1: Flash Memory Address (FMA), offset 0x000

During a write operation, this register contains a 4-byte-aligned address and specifies where the data is written. During erase operations, this register contains a 1 KB-aligned address and specifies which page is erased. Note that the alignment requirements must be met by software or the results of the operation are unpredictable.

Flash Memory Address (FMA)

Base 0x400F.D000

Offset 0x0000 Type R/W, reset 0x0000.0000

Address offset in flash where operation is performed, except for nonvolatile registers (see "Nonvolatile Register Programming" on page 115 for details on values for this field).

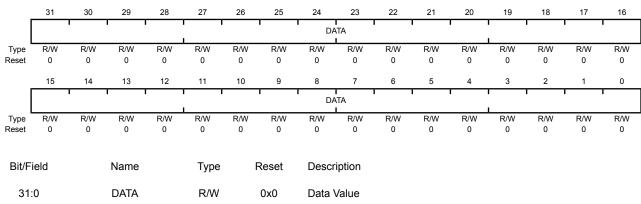

Register 2: Flash Memory Data (FMD), offset 0x004

This register contains the data to be written during the programming cycle or read during the read cycle. Note that the contents of this register are undefined for a read access of an execute-only block. This register is not used during the erase cycles.

Flash Memory Data (FMD)

Base 0x400F.D000

Offset 0x004 Type R/W, reset 0x0000.0000

Data value for write operation.

Register 3: Flash Memory Control (FMC), offset 0x008

When this register is written, the flash controller initiates the appropriate access cycle for the location specified by the Flash Memory Address (FMA) register (see page 117). If the access is a write access, the data contained in the Flash Memory Data (FMD) register (see page 118) is written.

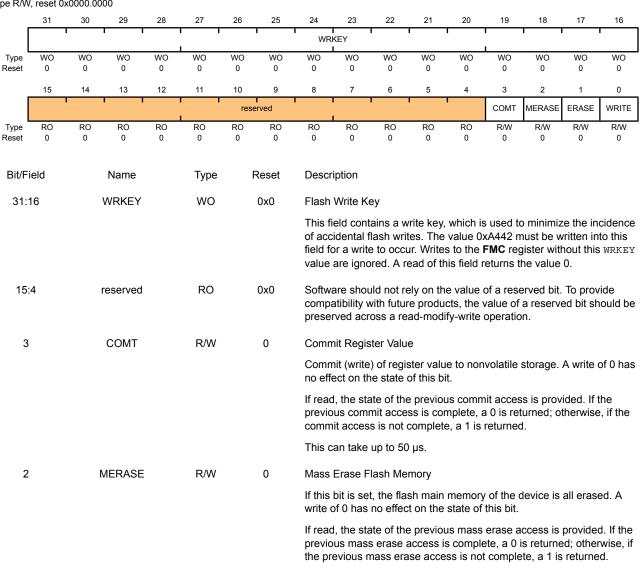

This is the final register written and initiates the memory operation. There are four control bits in the lower byte of this register that, when set, initiate the memory operation. The most used of these register bits are the ERASE and WRITE bits.

It is a programming error to write multiple control bits and the results of such an operation are unpredictable.

Flash Memory Control (FMC)

Base 0x400F.D000 Offset 0x008

Type R/W, reset 0x0000.0000

This can take up to 250 ms.

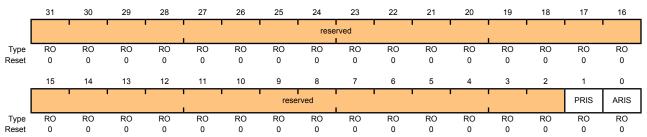

Bit/Field	Name	Туре	Reset	Description
1	ERASE	R/W	0	Erase a Page of Flash Memory
				If this bit is set, the page of flash main memory as specified by the contents of FMA is erased. A write of 0 has no effect on the state of this bit.
				If read, the state of the previous erase access is provided. If the previous erase access is complete, a 0 is returned; otherwise, if the previous erase access is not complete, a 1 is returned.
				This can take up to 25 ms.
0	WRITE	R/W	0	Write a Word into Flash Memory
				If this bit is set, the data stored in FMD is written into the location as specified by the contents of FMA . A write of 0 has no effect on the state of this bit.
				If read, the state of the previous write update is provided. If the previous write access is complete, a 0 is returned; otherwise, if the write access is not complete, a 1 is returned.
				This can take up to 50 µs.

Register 4: Flash Controller Raw Interrupt Status (FCRIS), offset 0x00C

This register indicates that the flash controller has an interrupt condition. An interrupt is only signaled if the corresponding **FCIM** register bit is set.

Flash Controller Raw Interrupt Status (FCRIS)

Base 0x400F.D000 Offset 0x00C Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	PRIS	RO	0	Programming Raw Interrupt Status
				This bit indicates the current state of the programming cycle. If set, the programming cycle completed; if cleared, the programming cycle has not completed. Programming cycles are either write or erase actions generated through the Flash Memory Control (FMC) register bits (see page 119).
0	ARIS	RO	0	Access Raw Interrupt Status

This bit indicates if the flash was improperly accessed. If set, the program tried to access the flash counter to the policy as set in the Flash Memory Protection Read Enable (FMPREn) and Flash Memory Protection Program Enable (FMPPEn) registers. Otherwise, no access has tried to improperly access the flash.

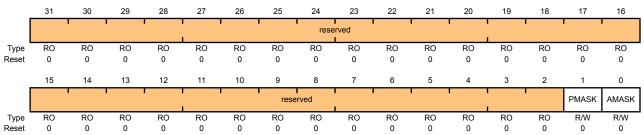

Register 5: Flash Controller Interrupt Mask (FCIM), offset 0x010

This register controls whether the flash controller generates interrupts to the controller.

Flash Controller Interrupt Mask (FCIM)

Base 0x400F.D000 Offset 0x010

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	PMASK	R/W	0	Programming Interrupt Mask
				This bit controls the reporting of the programming raw interrupt status to the controller. If set, a programming-generated interrupt is promoted to the controller. Otherwise, interrupts are recorded but suppressed from the controller.
0	AMASK	R/W	0	Access Interrupt Mask

This bit controls the reporting of the access raw interrupt status to the controller. If set, an access-generated interrupt is promoted to the controller. Otherwise, interrupts are recorded but suppressed from the controller.

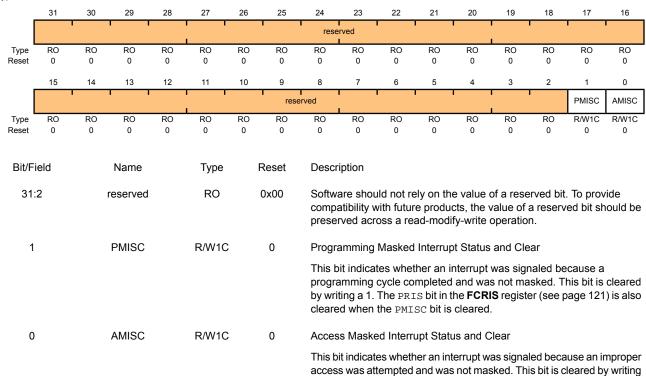

Register 6: Flash Controller Masked Interrupt Status and Clear (FCMISC), offset 0x014

This register provides two functions. First, it reports the cause of an interrupt by indicating which interrupt source or sources are signalling the interrupt. Second, it serves as the method to clear the interrupt reporting.

Flash Controller Masked Interrupt Status and Clear (FCMISC)

Base 0x400F.D000

Offset 0x014
Type R/W1C, reset 0x0000.0000

7.6 Flash Register Descriptions (System Control Offset)

The remainder of this section lists and describes the Flash Memory registers, in numerical order by address offset. Registers in this section are relative to the System Control base address of 0x400F.E000.

bit is cleared.

a 1. The ARIS bit in the FCRIS register is also cleared when the AMISC

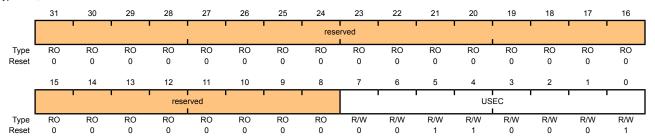

Register 7: USec Reload (USECRL), offset 0x140

Note: Offset is relative to System Control base address of 0x400F.E000

This register is provided as a means of creating a 1-µs tick divider reload value for the flash controller. The internal flash has specific minimum and maximum requirements on the length of time the high voltage write pulse can be applied. It is required that this register contain the operating frequency (in MHz -1) whenever the flash is being erased or programmed. The user is required to change this value if the clocking conditions are changed for a flash erase/program operation.

USec Reload (USECRL)

Base 0x400F.E000 Offset 0x140 Type R/W, reset 0x31

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	USEC	R/W	0x31	Microsecond Reload Value

MHz -1 of the controller clock when the flash is being erased or programmed.

 $\tt USEC$ should be set to 0x31 (50 MHz) whenever the flash is being erased or programmed.

Register 8: Flash Memory Protection Read Enable 0 (FMPRE0), offset 0x130 and 0x200

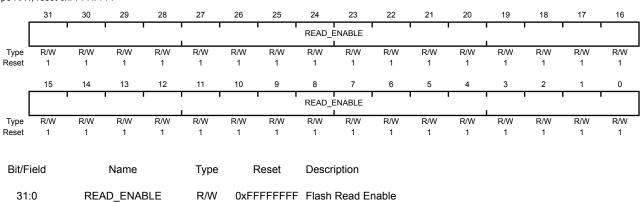

Note: This register is aliased for backwards compatability.

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Read Enable 0 (FMPRE0)

Base 0x400F.D000 Offset 0x130 and 0x200 Type R/W, reset 0xFFFF.FFFF

Enables 2-KB flash blocks to be executed or read. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

Value Description

0xFFFFFFF Enables 96 KB of flash.

Register 9: Flash Memory Protection Program Enable 0 (FMPPE0), offset 0x134 and 0x400

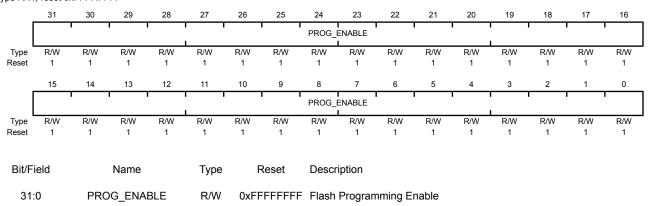

Note: This register is aliased for backwards compatability.

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Program Enable 0 (FMPPE0)

Base 0x400F.D000 Offset 0x134 and 0x400 Type R/W, reset 0xFFFF.FFFF

Configures 2-KB flash blocks to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

Value Description
0xFFFFFFF Enables 96 KB of flash.

Register 10: User Debug (USER_DBG), offset 0x1D0

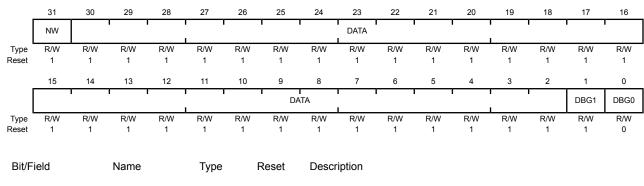

Note: Offset is relative to System Control base address of 0x400FE000.

This register provides a write-once mechanism to disable external debugger access to the device in addition to 27 additional bits of user-defined data. The DBG0 bit (bit 0) is set to 0 from the factory and the DBG1 bit (bit 1) is set to 1, which enables external debuggers. Changing the DBG1 bit to 0 disables any external debugger access to the device permanently, starting with the next power-up cycle of the device. The NOTWRITTEN bit (bit 31) indicates that the register is available to be written and is controlled through hardware to ensure that the register is only written once.

User Debug (USER DBG)

Base 0x400F.E000 Offset 0x1D0

Type R/W, reset 0xFFFF.FFFE

31	NW	R/W	1	User Debug Not Written Specifies that this 32-bit dword has not been written.
30:2	DATA	R/W	0x1FFFFFFF	User Data Contains the user data value. This field is initialized to all 1s and can only be written once.
1	DBG1	R/W	1	Debug Control 1 The DBG1 bit must be 1 and DBG0 must be 0 for debug to be available.
0	DBG0	R/W	0	Debug Control 0

The DBG1 bit must be 1 and DBG0 must be 0 for debug to be available.

Register 11: User Register 0 (USER_REG0), offset 0x1E0

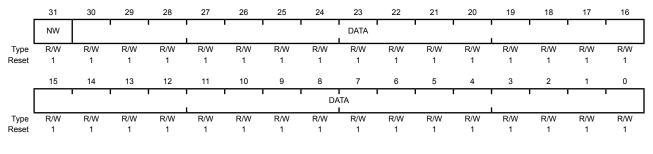

Note: Offset is relative to System Control base address of 0x400FE000.

This register provides 31 bits of user-defined data that is non-volatile and can only be written once. Bit 31 indicates that the register is available to be written and is controlled through hardware to ensure that the register is only written once. The write-once characteristics of this register are useful for keeping static information like communication addresses that need to be unique per part and would otherwise require an external EEPROM or other non-volatile device.

User Register 0 (USER_REG0)

Base 0x400F.E000 Offset 0x1E0

Type R/W, reset 0xFFFF.FFF

Bit/Field	Name	Туре	Reset	Description
31	NW	R/W	1	Not Written
				Specifies that this 32-bit dword has not been written.
30:0	DATA	R/W	0x7FFFFFF	User Data

Contains the user data value. This field is initialized to all 1s and can only be written once.

Register 12: User Register 1 (USER_REG1), offset 0x1E4

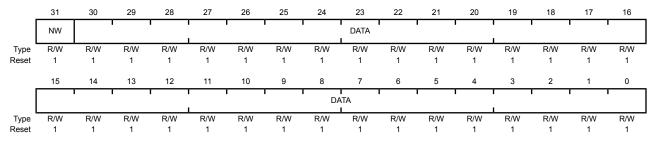

Note: Offset is relative to System Control base address of 0x400FE000.

This register provides 31 bits of user-defined data that is non-volatile and can only be written once. Bit 31 indicates that the register is available to be written and is controlled through hardware to ensure that the register is only written once. The write-once characteristics of this register are useful for keeping static information like communication addresses that need to be unique per part and would otherwise require an external EEPROM or other non-volatile device.

User Register 1 (USER_REG1)

Base 0x400F.E000 Offset 0x1E4

Type R/W, reset 0xFFFF.FFF

Bit/Field	Name	Type	Reset	Description
31	NW	R/W	1	Not Written
				Specifies that this 32-bit dword has not been written.
30:0	DATA	R/W	0x7FFFFFF	User Data

Contains the user data value. This field is initialized to all 1s and can only be written once.

Register 13: Flash Memory Protection Read Enable 1 (FMPRE1), offset 0x204

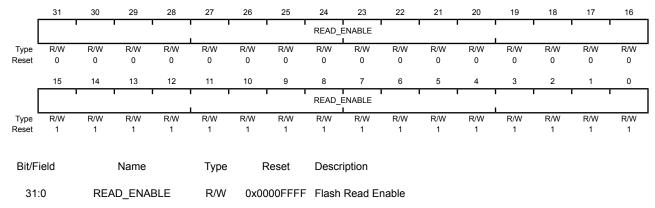

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Read Enable 1 (FMPRE1)

Base 0x400F.E000 Offset 0x204

Type R/W, reset 0x0000.FFFF

Enables 2-KB flash blocks to be executed or read. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

Value Description

0x0000FFFF Enables 96 KB of flash.

Register 14: Flash Memory Protection Read Enable 2 (FMPRE2), offset 0x208

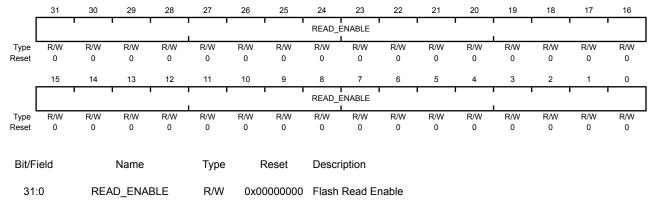

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Read Enable 2 (FMPRE2)

Base 0x400F.E000 Offset 0x208

Type R/W, reset 0x0000.0000

Enables 2-KB flash blocks to be executed or read. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

Value Description

0x00000000 Enables 96 KB of flash.

Register 15: Flash Memory Protection Read Enable 3 (FMPRE3), offset 0x20C

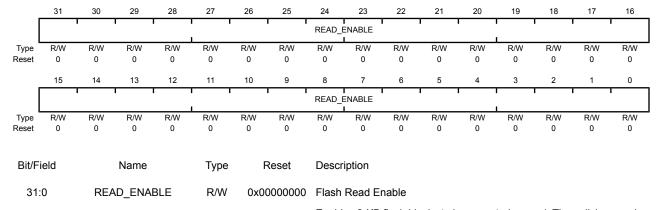

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Read Enable 3 (FMPRE3)

Base 0x400F.E000 Offset 0x20C

Type R/W, reset 0x0000.0000

Enables 2-KB flash blocks to be executed or read. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

Value Description
0x000000000 Enables 96 KB of flash.

Register 16: Flash Memory Protection Program Enable 1 (FMPPE1), offset 0x404

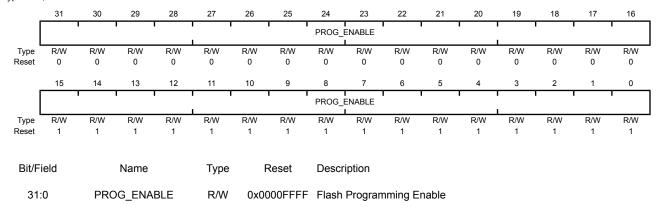

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Program Enable 1 (FMPPE1)

Base 0x400F.E000 Offset 0x404

Configures 2-KB flash blocks to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

Value Description

0x0000FFFF Enables 96 KB of flash.

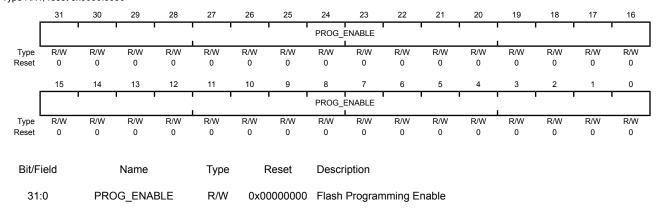

Register 17: Flash Memory Protection Program Enable 2 (FMPPE2), offset 0x408

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Program Enable 2 (FMPPE2)

Base 0x400F.E000 Offset 0x408 Type R/W, reset 0x0000.0000

Configures 2-KB flash blocks to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

Value Description

0x00000000 Enables 96 KB of flash.

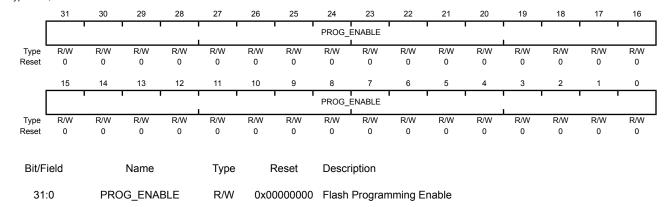

Register 18: Flash Memory Protection Program Enable 3 (FMPPE3), offset 0x40C

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Program Enable 3 (FMPPE3)

Base 0x400F.E000 Offset 0x40C Type R/W, reset 0x0000.0000

Configures 2-KB flash blocks to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".

Value Description

0x00000000 Enables 96 KB of flash.

8 General-Purpose Input/Outputs (GPIOs)

The GPIO module is composed of eight physical GPIO blocks, each corresponding to an individual GPIO port (Port A, Port B, Port C, Port D, Port E, Port F, Port G, and Port H). The GPIO module is FiRM-compliant and supports 5-34 programmable input/output pins, depending on the peripherals being used.

The GPIO module has the following features:

- Programmable control for GPIO interrupts
 - Interrupt generation masking
 - Edge-triggered on rising, falling, or both
 - Level-sensitive on High or Low values
- 5-V-tolerant input/outputs
- Bit masking in both read and write operations through address lines
- Programmable control for GPIO pad configuration
 - Weak pull-up or pull-down resistors
 - 2-mA, 4-mA, and 8-mA pad drive
 - Slew rate control for the 8-mA drive
 - Open drain enables
 - Digital input enables

8.1 Functional Description

Important: All GPIO pins are tri-stated by default (GPIOAFSEL=0, GPIODEN=0, GPIOPDR=0, and GPIOPUR=0), with the exception of the five JTAG/SWD pins (PB7 and PC[3:0]). The JTAG/SWD pins default to their JTAG/SWD functionality (GPIOAFSEL=1, GPIODEN=1 and GPIOPUR=1). A Power-On-Reset (POR) or asserting RST puts both groups of pins back to their default state.

Each GPIO port is a separate hardware instantiation of the same physical block (see Figure 8-1 on page 137). The LM3S2432 microcontroller contains eight ports and thus eight of these physical GPIO blocks.

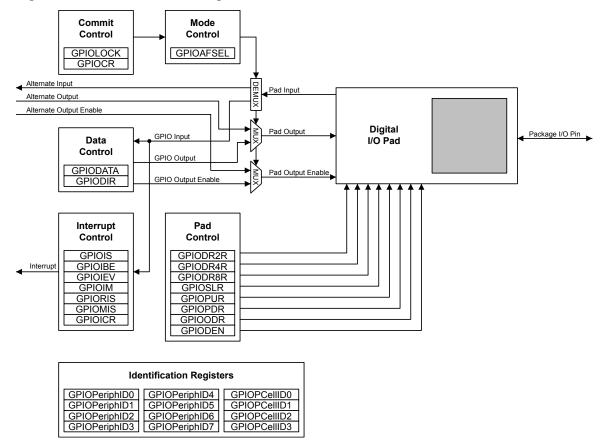

Figure 8-1. GPIO Port Block Diagram

8.1.1 Data Control

The data control registers allow software to configure the operational modes of the GPIOs. The data direction register configures the GPIO as an input or an output while the data register either captures incoming data or drives it out to the pads.

8.1.1.1 Data Direction Operation

The **GPIO Direction (GPIODIR)** register (see page 144) is used to configure each individual pin as an input or output. When the data direction bit is set to 0, the GPIO is configured as an input and the corresponding data register bit will capture and store the value on the GPIO port. When the data direction bit is set to 1, the GPIO is configured as an output and the corresponding data register bit will be driven out on the GPIO port.

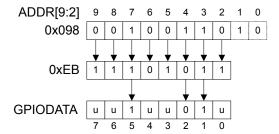

8.1.1.2 Data Register Operation

To aid in the efficiency of software, the GPIO ports allow for the modification of individual bits in the **GPIO Data (GPIODATA)** register (see page 143) by using bits [9:2] of the address bus as a mask. This allows software drivers to modify individual GPIO pins in a single instruction, without affecting the state of the other pins. This is in contrast to the "typical" method of doing a read-modify-write operation to set or clear an individual GPIO pin. To accommodate this feature, the **GPIODATA** register covers 256 locations in the memory map.

During a write, if the address bit associated with that data bit is set to 1, the value of the **GPIODATA** register is altered. If it is cleared to 0, it is left unchanged.

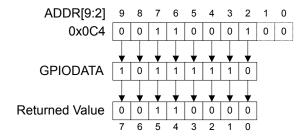

For example, writing a value of 0xEB to the address GPIODATA + 0x098 would yield as shown in Figure 8-2 on page 138, where u is data unchanged by the write.

Figure 8-2. GPIODATA Write Example

During a read, if the address bit associated with the data bit is set to 1, the value is read. If the address bit associated with the data bit is set to 0, it is read as a zero, regardless of its actual value. For example, reading address GPIODATA + 0x0C4 yields as shown in Figure 8-3 on page 138.

Figure 8-3. GPIODATA Read Example

8.1.2 Interrupt Control

The interrupt capabilities of each GPIO port are controlled by a set of seven registers. With these registers, it is possible to select the source of the interrupt, its polarity, and the edge properties. When one or more GPIO inputs cause an interrupt, a single interrupt output is sent to the interrupt controller for the entire GPIO port. For edge-triggered interrupts, software must clear the interrupt to enable any further interrupts. For a level-sensitive interrupt, it is assumed that the external source holds the level constant for the interrupt to be recognized by the controller.

Three registers are required to define the edge or sense that causes interrupts:

- GPIO Interrupt Sense (GPIOIS) register (see page 145)
- GPIO Interrupt Both Edges (GPIOIBE) register (see page 146)
- GPIO Interrupt Event (GPIOIEV) register (see page 147)

Interrupts are enabled/disabled via the GPIO Interrupt Mask (GPIOIM) register (see page 148).

When an interrupt condition occurs, the state of the interrupt signal can be viewed in two locations: the **GPIO Raw Interrupt Status (GPIORIS)** and **GPIO Masked Interrupt Status (GPIOMIS)** registers (see page 149 and page 150). As the name implies, the **GPIOMIS** register only shows interrupt conditions that are allowed to be passed to the controller. The **GPIORIS** register indicates that a GPIO pin meets the conditions for an interrupt, but has not necessarily been sent to the controller.

In addition to providing GPIO functionality, PB4 can also be used as an external trigger for the ADC. If PB4 is configured as a non-masked interrupt pin (GPIOIM is set to 1), not only is an interrupt for PortB generated, but an external trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated.

If no other PortB pins are being used to generate interrupts, the ARM Integrated Nested Vectored Interrupt Controller (NVIC) Interrupt Set Enable (SETNA) register can disable the PortB interrupts and the ADC interrupt can be used to read back the converted data. Otherwise, the PortB interrupt handler needs to ignore and clear interrupts on B4, and wait for the ADC interrupt or the ADC interrupt needs to be disabled in the SETNA register and the PortB interrupt handler polls the ADC registers until the conversion is completed.

Interrupts are cleared by writing a 1 to the GPIO Interrupt Clear (GPIOICR) register (see page 151).

When programming the following interrupt control registers, the interrupts should be masked (**GPIOIM** set to 0). Writing any value to an interrupt control register (**GPIOIS**, **GPIOIBE**, or **GPIOIEV**) can generate a spurious interrupt if the corresponding bits are enabled.

8.1.3 Mode Control

The GPIO pins can be controlled by either hardware or software. When hardware control is enabled via the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 152), the pin state is controlled by its alternate function (that is, the peripheral). Software control corresponds to GPIO mode, where the **GPIODATA** register is used to read/write the corresponding pins.

8.1.4 Commit Control

The commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 152) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 162) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 163) have been set to 1.

8.1.5 Pad Control

The pad control registers allow for GPIO pad configuration by software based on the application requirements. The pad control registers include the **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODDR**, **GPIODDR**, **GPIODDR**, and **GPIODEN** registers.

8.1.6 Identification

The identification registers configured at reset allow software to detect and identify the module as a GPIO block. The identification registers include the **GPIOPeriphID0-GPIOPeriphID7** registers as well as the **GPIOPCeIIID0-GPIOPCeIIID3** registers.

8.2 Initialization and Configuration

To use the GPIO, the peripheral clock must be enabled by setting the appropriate GPIO Port bit field (GPIOn) in the **RCGC2** register.

On reset, all GPIO pins (except for the five JTAG pins) are configured out of reset to be undriven (tristate): **GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, and **GPIOPUR**=0. Table 8-1 on page 140 shows all possible configurations of the GPIO pads and the control register settings required to achieve them. Table 8-2 on page 140 shows how a rising edge interrupt would be configured for pin 2 of a GPIO port.

Table 8-1. GPIO Pad Configuration Examples

Configuration	GPIO Register Bit Value ^a											
	AFSEL	DIR	ODR	DEN	PUR	PDR	DR2R	DR4R	DR8R	SLR		
Digital Input (GPIO)	0	0	0	1	?	?	Х	Х	Х	Х		
Digital Output (GPIO)	0	1	0	1	?	?	?	?	?	?		
Open Drain Input (GPIO)	0	0	1	1	Х	Х	Х	Х	Х	Х		
Open Drain Output (GPIO)	0	1	1	1	Х	Х	?	?	?	?		
Open Drain Input/Output (I ² C)	1	Х	1	1	Х	Х	?	?	?	?		
Digital Input (Timer CCP)	1	Х	0	1	?	?	Х	Х	Х	Х		
Digital Output (PWM)	1	Х	0	1	?	?	?	?	?	?		
Digital Output (Timer PWM)	1	Х	0	1	?	?	?	?	?	?		
Digital Input/Output (SSI)	1	Х	0	1	?	?	?	?	?	?		
Digital Input/Output (UART)	1	Х	0	1	?	?	?	?	?	?

Digital Output (Comparator)	1	Х	0	1	?	?	?	?	?	?		

a. X=Ignored (don't care bit)

Table 8-2. GPIO Interrupt Configuration Example

	Desired	Pin 2 Bit Value ^a									
	Interrupt Event Trigger	7	6	5	4	3	2	1	0		
GPIOIS	0=edge 1=level	Х	Х	Х	Х	Х	0	Х	Х		
GPIOIBE	0=single edge 1=both edges	Х	Х	Х	Х	Х	0	Х	Х		
GPIOIEV	0=Low level, or negative edge 1=High level, or positive edge	Х	X	Х	X	Х	1	X	Х		
GPIOIM	0=masked 1=not masked	0	0	0	0	0	1	0	0		

a. X=Ignored (don't care bit)

^{?=}Can be either 0 or 1, depending on the configuration

8.3 Register Map

Table 8-3 on page 141 lists the GPIO registers. The offset listed is a hexadecimal increment to the register's address, relative to that GPIO port's base address:

GPIO Port A: 0x4000.4000

GPIO Port B: 0x4000.5000

GPIO Port C: 0x4000.6000

GPIO Port D: 0x4000.7000

GPIO Port E: 0x4002.4000

GPIO Port F: 0x4002.5000

GPIO Port G: 0x4002.6000

GPIO Port H: 0x4002.7000

Important: The GPIO registers in this chapter are duplicated in each GPIO block, however, depending on the block, all eight bits may not be connected to a GPIO pad. In those cases, writing to those unconnected bits has no effect and reading those unconnected bits returns no meaningful data.

Note: The default reset value for the **GPIOAFSEL**, **GPIOPUR**, and **GPIODEN** registers are 0x0000.0000 for all GPIO pins, with the exception of the five JTAG/SWD pins (PB7 and PC[3:0]). These five pins default to JTAG/SWD functionality. Because of this, the default reset value of these registers for GPIO Port B is 0x0000.0080 while the default reset value for Port C is 0x0000.000F.

The default register type for the **GPIOCR** register is RO for all GPIO pins, with the exception of the five JTAG/SWD pins (PB7 and PC[3:0]). These five pins are currently the only GPIOs that are protected by the **GPIOCR** register. Because of this, the register type for GPIO Port B7 and GPIO Port C[3:0] is R/W.

The default reset value for the **GPIOCR** register is 0x0000.00FF for all GPIO pins, with the exception of the five JTAG/SWD pins (PB7 and PC[3:0]). To ensure that the JTAG port is not accidentally programmed as a GPIO, these five pins default to non-commitable. Because of this, the default reset value of **GPIOCR** for GPIO Port B is 0x0000.007F while the default reset value of **GPIOCR** for Port C is 0x0000.00F0.

Table 8-3. GPIO Register Map

8.4 Register Descriptions

The remainder of this section lists and describes the GPIO registers, in numerical order by address offset.

Register 1: GPIO Data (GPIODATA), offset 0x000

The **GPIODATA** register is the data register. In software control mode, values written in the **GPIODATA** register are transferred onto the GPIO port pins if the respective pins have been configured as outputs through the **GPIO Direction (GPIODIR)** register (see page 144).

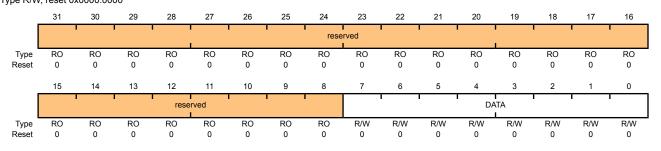

In order to write to **GPIODATA**, the corresponding bits in the mask, resulting from the address bus bits [9:2], must be High. Otherwise, the bit values remain unchanged by the write.

Similarly, the values read from this register are determined for each bit by the mask bit derived from the address used to access the data register, bits [9:2]. Bits that are 1 in the address mask cause the corresponding bits in **GPIODATA** to be read, and bits that are 0 in the address mask cause the corresponding bits in **GPIODATA** to be read as 0, regardless of their value.

A read from **GPIODATA** returns the last bit value written if the respective pins are configured as outputs, or it returns the value on the corresponding input pin when these are configured as inputs. All bits are cleared by a reset.

GPIO Data (GPIODATA)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.7000 GPIO Port H base: 0x4002.7000 GFISE 0x0000 Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DATA	R/W	0x00	GPIO Data

This register is virtually mapped to 256 locations in the address space. To facilitate the reading and writing of data to these registers by independent drivers, the data read from and the data written to the registers are masked by the eight address lines $\mathtt{ipaddr}[9:2]$. Reads from this register return its current state. Writes to this register only affect bits that are not masked by $\mathtt{ipaddr}[9:2]$ and are configured as outputs. See "Data Register Operation" on page 137 for examples of reads and writes.

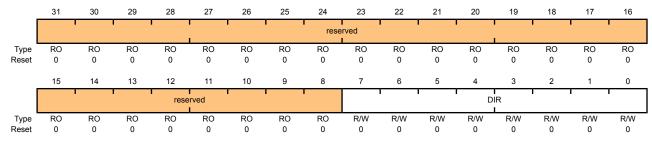

Register 2: GPIO Direction (GPIODIR), offset 0x400

The **GPIODIR** register is the data direction register. Bits set to 1 in the **GPIODIR** register configure the corresponding pin to be an output, while bits set to 0 configure the pins to be inputs. All bits are cleared by a reset, meaning all GPIO pins are inputs by default.

GPIO Direction (GPIODIR)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x400

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DIR	R/W	0x00	GPIO Data Direction

The DIR values are defined as follows:

Value Description

- 0 Pins are inputs.
- Pins are outputs.

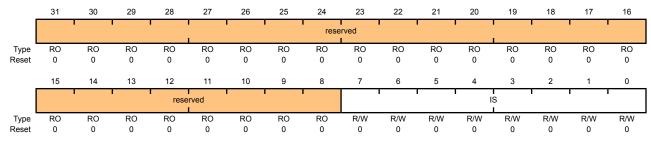

Register 3: GPIO Interrupt Sense (GPIOIS), offset 0x404

The **GPIOIS** register is the interrupt sense register. Bits set to 1 in **GPIOIS** configure the corresponding pins to detect levels, while bits set to 0 configure the pins to detect edges. All bits are cleared by a reset.

GPIO Interrupt Sense (GPIOIS)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x4040

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IS	R/W	0x00	GPIO Interrupt Sense

The IS values are defined as follows:

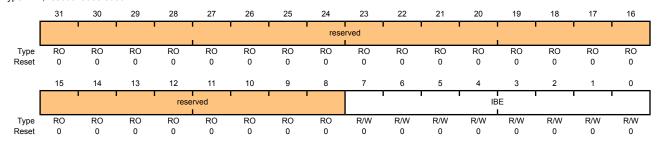

- 0 Edge on corresponding pin is detected (edge-sensitive).
- 1 Level on corresponding pin is detected (level-sensitive).

Register 4: GPIO Interrupt Both Edges (GPIOIBE), offset 0x408

The **GPIOIBE** register is the interrupt both-edges register. When the corresponding bit in the **GPIO Interrupt Sense (GPIOIS)** register (see page 145) is set to detect edges, bits set to High in **GPIOIBE** configure the corresponding pin to detect both rising and falling edges, regardless of the corresponding bit in the **GPIO Interrupt Event (GPIOIEV)** register (see page 147). Clearing a bit configures the pin to be controlled by **GPIOIEV**. All bits are cleared by a reset.

GPIO Interrupt Both Edges (GPIOIBE)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x408 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IBE	R/W	0x00	GPIO Interrupt Both Edges

The IBE values are defined as follows:

Value Description

- Interrupt generation is controlled by the GPIO Interrupt Event (GPIOIEV) register (see page 147).
- 1 Both edges on the corresponding pin trigger an interrupt.

Note: Single edge is determined by the corresponding bit in **GPIOIEV**.

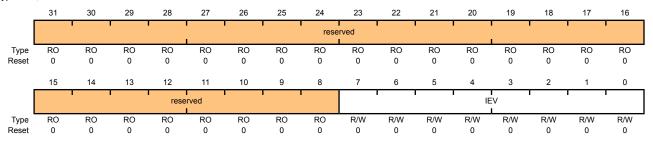

Register 5: GPIO Interrupt Event (GPIOIEV), offset 0x40C

The **GPIOIEV** register is the interrupt event register. Bits set to High in **GPIOIEV** configure the corresponding pin to detect rising edges or high levels, depending on the corresponding bit value in the **GPIO Interrupt Sense (GPIOIS)** register (see page 145). Clearing a bit configures the pin to detect falling edges or low levels, depending on the corresponding bit value in **GPIOIS**. All bits are cleared by a reset.

GPIO Interrupt Event (GPIOIEV)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x400C

Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IFV	R/W	0x00	GPIO Interrunt Event

The IEV values are defined as follows:

- 0 Falling edge or Low levels on corresponding pins trigger interrupts.
- Rising edge or High levels on corresponding pins trigger interrupts.

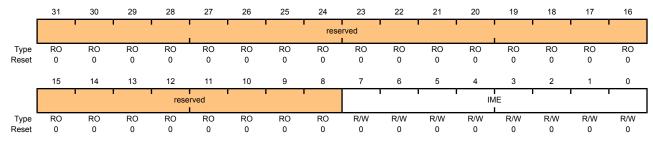

Register 6: GPIO Interrupt Mask (GPIOIM), offset 0x410

The **GPIOIM** register is the interrupt mask register. Bits set to High in **GPIOIM** allow the corresponding pins to trigger their individual interrupts and the combined GPIOINTR line. Clearing a bit disables interrupt triggering on that pin. All bits are cleared by a reset.

GPIO Interrupt Mask (GPIOIM)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x410

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IME	R/W	0x00	GPIO Interrupt Mask Enable

The IME values are defined as follows:

- 0 Corresponding pin interrupt is masked.
- 1 Corresponding pin interrupt is not masked.

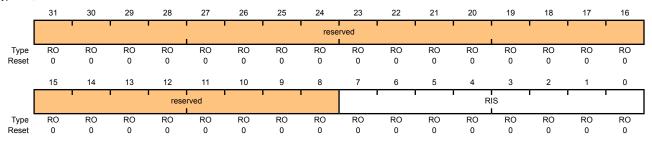

Register 7: GPIO Raw Interrupt Status (GPIORIS), offset 0x414

The **GPIORIS** register is the raw interrupt status register. Bits read High in **GPIORIS** reflect the status of interrupt trigger conditions detected (raw, prior to masking), indicating that all the requirements have been met, before they are finally allowed to trigger by the **GPIO Interrupt Mask (GPIOIM)** register (see page 148). Bits read as zero indicate that corresponding input pins have not initiated an interrupt. All bits are cleared by a reset.

GPIO Raw Interrupt Status (GPIORIS)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 OFISE 0x414

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	RIS	RO	0x00	GPIO Interrupt Raw Status

Reflects the status of interrupt trigger condition detection on pins (raw, prior to masking).

The RIS values are defined as follows:

- 0 Corresponding pin interrupt requirements not met.
- 1 Corresponding pin interrupt has met requirements.

Register 8: GPIO Masked Interrupt Status (GPIOMIS), offset 0x418

The **GPIOMIS** register is the masked interrupt status register. Bits read High in **GPIOMIS** reflect the status of input lines triggering an interrupt. Bits read as Low indicate that either no interrupt has been generated, or the interrupt is masked.

In addition to providing GPIO functionality, PB4 can also be used as an external trigger for the ADC. If PB4 is configured as a non-masked interrupt pin (GPIOIM is set to 1), not only is an interrupt for PortB generated, but an external trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated.

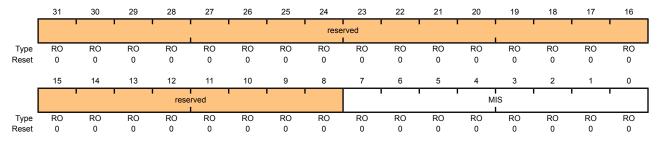

If no other PortB pins are being used to generate interrupts, the ARM Integrated Nested Vectored Interrupt Controller (NVIC) Interrupt Set Enable (SETNA) register can disable the PortB interrupts and the ADC interrupt can be used to read back the converted data. Otherwise, the PortB interrupt handler needs to ignore and clear interrupts on B4, and wait for the ADC interrupt or the ADC interrupt needs to be disabled in the SETNA register and the PortB interrupt handler polls the ADC registers until the conversion is completed.

GPIOMIS is the state of the interrupt after masking.

GPIO Masked Interrupt Status (GPIOMIS)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.7000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 OFISE 0x418

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	MIS	RO	0x00	GPIO Masked Interrupt Status

Masked value of interrupt due to corresponding pin.

The MIS values are defined as follows:

- 0 Corresponding GPIO line interrupt not active.
- 1 Corresponding GPIO line asserting interrupt.

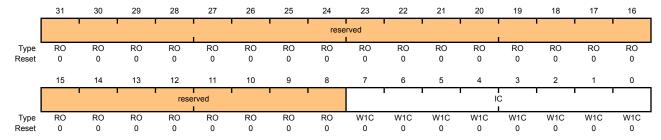

Register 9: GPIO Interrupt Clear (GPIOICR), offset 0x41C

The **GPIOICR** register is the interrupt clear register. Writing a 1 to a bit in this register clears the corresponding interrupt edge detection logic register. Writing a 0 has no effect.

GPIO Interrupt Clear (GPIOICR)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x41C

Type W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IC	W1C	0x00	GPIO Interrupt Clear

The IC values are defined as follows:

- 0 Corresponding interrupt is unaffected.
- Corresponding interrupt is cleared.

Register 10: GPIO Alternate Function Select (GPIOAFSEL), offset 0x420

The **GPIOAFSEL** register is the mode control select register. Writing a 1 to any bit in this register selects the hardware control for the corresponding GPIO line. All bits are cleared by a reset, therefore no GPIO line is set to hardware control by default.

The commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Writes to protected bits of the GPIO Alternate Function Select (GPIOAFSEL) register (see page 152) are not committed to storage unless the GPIO Lock (GPIOLOCK) register (see page 162) has been unlocked and the appropriate bits of the GPIO Commit (GPIOCR) register (see page 163) have been set to 1.

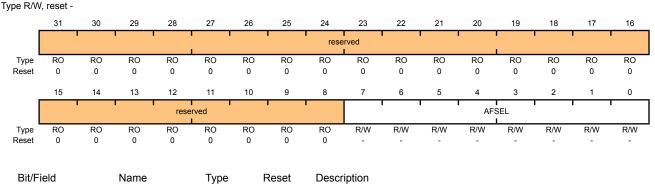

Important: All GPIO pins are tri-stated by default (GPIOAFSEL=0, GPIODEN=0, GPIOPDR=0, and GPIOPUR=0), with the exception of the five JTAG/SWD pins (PB7 and PC[3:0]). The JTAG/SWD pins default to their JTAG/SWD functionality (GPIOAFSEL=1. GPIODEN=1 and GPIOPUR=1). A Power-On-Reset (FOR) or asserting RST puts both groups of pins back to their default state.

Caution – If the JTAG pins are used as GPIOs in a design, PB7 and PC2 cannot have external pull-down resistors connected to both of them at the same time. If both pins are pulled Low during reset, the controller has unpredictable behavior. If this happens, remove one or both of the pull-down resistors, and apply RST or power-cycle the part.

In addition, it is possible to create a software sequence that prevents the debugger from connecting to the Stellaris® microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. This may lock the debugger out of the part. This can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.

GPIO Alternate Function Select (GPIOAFSEL)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x420

31:8 reserved RO 0x00 Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
7:0	AESEI	R/W	_	GPIO Alternate Function Select

The AFSEL values are defined as follows:

Value Description

- O Software control of corresponding GPIO line (GPIO mode).
- 1 Hardware control of corresponding GPIO line (alternate hardware function).

Note:

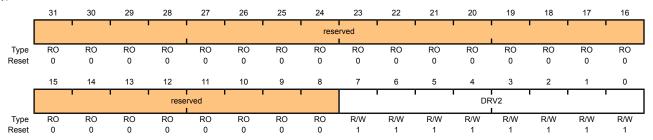

The default reset value for the **GPIOAFSEL**, **GPIOPUR**, and **GPIODEN** registers are 0x0000.0000 for all GPIO pins, with the exception of the five JTAG/SWD pins (PB7 and PC[3:0]). These five pins default to JTAG/SWD functionality. Because of this, the default reset value of these registers for GPIO Port B is 0x0000.0080 while the default reset value for Port C is 0x0000.000F.

Register 11: GPIO 2-mA Drive Select (GPIODR2R), offset 0x500

The **GPIODR2R** register is the 2-mA drive control register. It allows for each GPIO signal in the port to be individually configured without affecting the other pads. When writing a DRV2 bit for a GPIO signal, the corresponding DRV4 bit in the **GPIODR4R** register and the DRV8 bit in the **GPIODR8R** register are automatically cleared by hardware.

GPIO 2-mA Drive Select (GPIODR2R)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x500 Type R/W, reset 0x0000.00FF

Bit/Field	Name	Type	Reset	Description
Did Told	ramo	1,700	110001	2000.194011
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DRV2	R/W	0xFF	Output Pad 2-mA Drive Enable

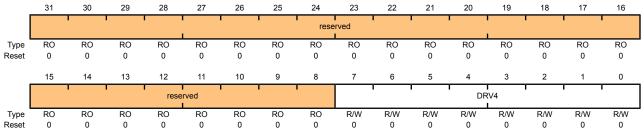

A write of 1 to either **GPIODR4[n]** or **GPIODR8[n]** clears the corresponding 2-mA enable bit. The change is effective on the second clock cycle after the write.

Register 12: GPIO 4-mA Drive Select (GPIODR4R), offset 0x504

The **GPIODR4R** register is the 4-mA drive control register. It allows for each GPIO signal in the port to be individually configured without affecting the other pads. When writing the DRV4 bit for a GPIO signal, the corresponding DRV2 bit in the **GPIODR2R** register and the DRV8 bit in the **GPIODR8R** register are automatically cleared by hardware.

GPIO 4-mA Drive Select (GPIODR4R)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x504 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DRV4	R/W	0x00	Output Pad 4-mA Drive Enable

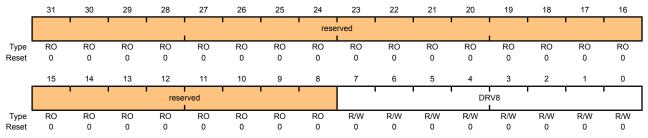

A write of 1 to either **GPIODR2[n]** or **GPIODR8[n]** clears the corresponding 4-mA enable bit. The change is effective on the second clock cycle after the write.

Register 13: GPIO 8-mA Drive Select (GPIODR8R), offset 0x508

The **GPIODR8R** register is the 8-mA drive control register. It allows for each GPIO signal in the port to be individually configured without affecting the other pads. When writing the DRV8 bit for a GPIO signal, the corresponding DRV2 bit in the **GPIODR2R** register and the DRV4 bit in the **GPIODR4R** register are automatically cleared by hardware.

GPIO 8-mA Drive Select (GPIODR8R)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x508 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DRV8	R/W	0x00	Output Pad 8-mA Drive Enable

A write of 1 to either **GPIODR2[n]** or **GPIODR4[n]** clears the corresponding 8-mA enable bit. The change is effective on the second clock cycle after the write.

Register 14: GPIO Open Drain Select (GPIOODR), offset 0x50C

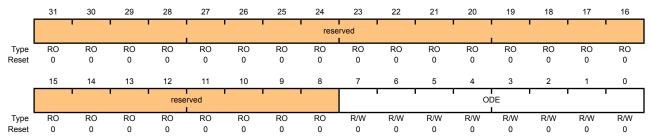

The **GPIOODR** register is the open drain control register. Setting a bit in this register enables the open drain configuration of the corresponding GPIO pad. When open drain mode is enabled, the corresponding bit should also be set in the **GPIO Digital Input Enable (GPIODEN)** register (see page 161). Corresponding bits in the drive strength registers (**GPIODR2R**, **GPIODR4R**, **GPIODR8R**, and **GPIOSLR**) can be set to achieve the desired rise and fall times. The GPIO acts as an open drain input if the corresponding bit in the **GPIODIR** register is set to 0; and as an open drain output when set to 1.

When using the I²C module, the **GPIO Alternate Function Select (GPIOAFSEL)** register bit for PB2 and PB3 should be set to 1 (see examples in "Initialization and Configuration" on page 139).

GPIO Open Drain Select (GPIOODR)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 OFISE! 0x50C

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	ODE	R/W	0x00	Output Pad Open Drain Enable

The ODE values are defined as follows:

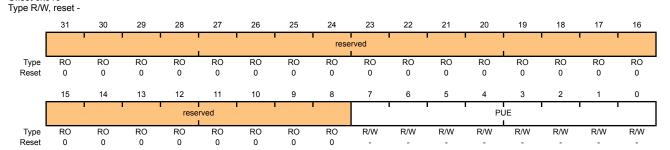

- 0 Open drain configuration is disabled.
- 1 Open drain configuration is enabled.

Register 15: GPIO Pull-Up Select (GPIOPUR), offset 0x510

The **GPIOPUR** register is the pull-up control register. When a bit is set to 1, it enables a weak pull-up resistor on the corresponding GPIO signal. Setting a bit in **GPIOPUR** automatically clears the corresponding bit in the **GPIO Pull-Down Select (GPIOPDR)** register (see page 159).

GPIO Pull-Up Select (GPIOPUR)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 OFISE 0x510

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PUE	R/W	_	Pad Weak Pull-Up Enable

A write of 1 to **GPIOPDR[n]** clears the corresponding **GPIOPUR[n]** enables. The change is effective on the second clock cycle after the write.

Note:

The default reset value for the **GPIOAFSEL**, **GPIOPUR**, and **GPIODEN** registers are 0x0000.0000 for all GPIO pins, with the exception of the five JTAG/SWD pins (PB7 and PC[3:0]). These five pins default to JTAG/SWD functionality. Because of this, the default reset value of these registers for GPIO Port B is 0x0000.0080 while the default reset value for Port C is 0x0000.000F.

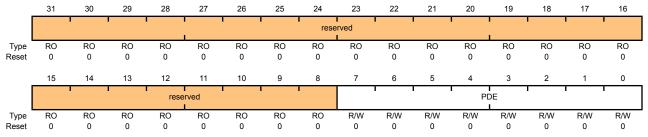

Register 16: GPIO Pull-Down Select (GPIOPDR), offset 0x514

The **GPIOPDR** register is the pull-down control register. When a bit is set to 1, it enables a weak pull-down resistor on the corresponding GPIO signal. Setting a bit in **GPIOPDR** automatically clears the corresponding bit in the **GPIO Pull-Up Select (GPIOPUR)** register (see page 158).

GPIO Pull-Down Select (GPIOPDR)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.5000 GPIO Port H base: 0x4002.7000 Offset 0x514

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	PDE	R/W	0x00	Pad Weak Pull-Down Enable

A write of 1 to **GPIOPUR[n]** clears the corresponding **GPIOPDR[n]** enables. The change is effective on the second clock cycle after the write.

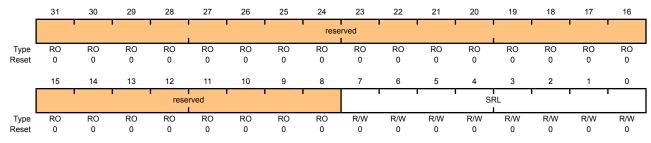

Register 17: GPIO Slew Rate Control Select (GPIOSLR), offset 0x518

The **GPIOSLR** register is the slew rate control register. Slew rate control is only available when using the 8-mA drive strength option via the **GPIO 8-mA Drive Select (GPIODR8R)** register (see page 156).

GPIO Slew Rate Control Select (GPIOSLR)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x518

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	SRL	R/W	0x00	Slew Rate Limit Enable (8-mA drive only)

The SRL values are defined as follows:

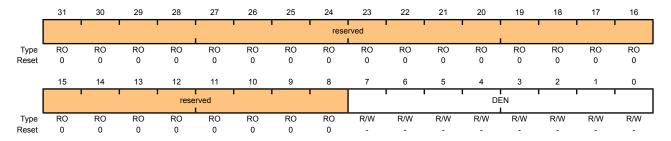

- Slew rate control disabled.
- Slew rate control enabled.

Register 18: GPIO Digital Enable (GPIODEN), offset 0x51C

The **GPIODEN** register is the digital enable register. By default, with the exception of the GPIO signals used for JTAG/SWD function, all other GPIO signals are configured out of reset to be undriven (tristate). Their digital function is disabled; they do not drive a logic value on the pin and they do not allow the pin voltage into the GPIO receiver. To use the pin in a digital function (either GPIO or alternate function), the corresponding GPIODEN bit must be set.

GPIO Digital Enable (GPIODEN)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x51C Type R/W, reset -

Bit/Field	Name	Туре	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DEN	R/W	_	Digital Enable

The DEN values are defined as follows:

Value Description

- Digital functions disabled.
- Digital functions enabled.

Note:

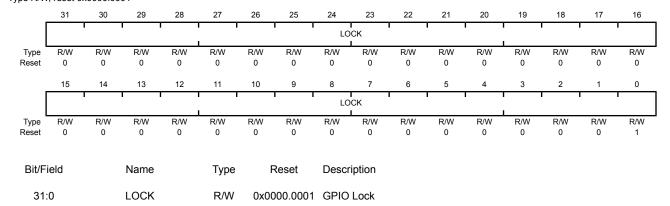

The default reset value for the GPIOAFSEL, **GPIOPUR**, and **GPIODEN** registers are 0x0000.0000 for all GPIO pins, with the exception of the five JTAG/SWD pins (PB7 and PC[3:0]). These five pins default to JTAG/SWD functionality. Because of this, the default reset value of these registers for GPIO Port B is 0x0000.0080 while the default reset value for Port C is 0x0000.000F.

Register 19: GPIO Lock (GPIOLOCK), offset 0x520

The **GPIOLOCK** register enables write access to the **GPIOCR** register (see page 163). Writing 0x1ACCE551 to the **GPIOLOCK** register will unlock the **GPIOCR** register. Writing any other value to the **GPIOLOCK** register re-enables the locked state. Reading the **GPIOLOCK** register returns the lock status rather than the 32-bit value that was previously written. Therefore, when write accesses are disabled, or locked, reading the **GPIOLOCK** register returns 0x00000001. When write accesses are enabled, or unlocked, reading the **GPIOLOCK** register returns 0x000000000.

GPIO Lock (GPIOLOCK)

GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000.5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000 GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000 GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000 Offset 0x520 Type R/W, reset 0x0000.0001

A write of the value 0x1ACCE551 unlocks the **GPIO Commit (GPIOCR)** register for write access. A write of any other value reapplies the lock, preventing any register updates. A read of this register returns the following values:

Value Description 0x0000.0001 locked 0x0000.0000 unlocked

Register 20: GPIO Commit (GPIOCR), offset 0x524

The GPIOCR register is the commit register. The value of the GPIOCR register determines which bits of the GPIOAFSEL register will be committed when a write to the GPIOAFSEL register is performed. If a bit in the GPIOCR register is a zero, the data being written to the corresponding bit in the GPIOAFSEL register will not be committed and will retain its previous value. If a bit in the **GPIOCR** register is a one, the data being written to the corresponding bit of the **GPIOAFSEL** register will be committed to the register and will reflect the new value.

The contents of the **GPIOCR** register can only be modified if the **GPIOLOCK** register is unlocked. Writes to the GPIOCR register will be ignored if the GPIOLOCK register is locked.

Important: This register is designed to prevent accidental programming of the GPIOAFSEL registers that control connectivity to the JTAG/SWD debug hardware. By initializing the bits of the GPIOCR register to 0 for PB7 and PC[3:0], the JTAG/SWD debug port can only be converted to GPIOs through a deliberate set of writes to the GPIOLOCK, GPIOCR, and **GPIOAFSEL** registers.

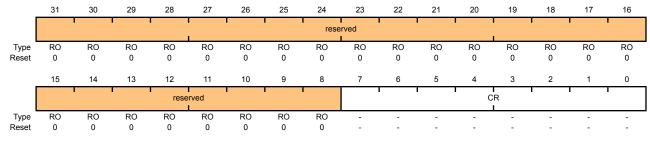

> Because this protection is currently only implemented on the JTAG/SWD pins on PB7 and PC[3:0], all of the other bits in the **GPIOCR** registers cannot be written with 0x0. These bits are hardwired to 0x1, ensuring that it is always possible to commit new values to the **GPIOAFSEL** register bits of these other pins.

GPIO Commit (GPIOCR) GPIO Port A base: 0x4000.4000 GPIO Port B base: 0x4000 5000 GPIO Port C base: 0x4000.6000 GPIO Port D base: 0x4000.7000

GPIO Port E base: 0x4002.4000 GPIO Port F base: 0x4002.5000

GPIO Port G base: 0x4002.6000 GPIO Port H base: 0x4002.7000

Offset 0x524 Type -, reset -

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
7:0	CR	_	_	GPIO Commit

On a bit-wise basis, any bit set allows the corresponding <code>GPIOAFSEL</code> bit to be set to its alternate function.

Note:

The default register type for the **GPIOCR** register is RO for all GPIO pins, with the exception of the five JTAG/SWD pins (PB7 and PC[3:0]). These five pins are currently the only GPIOs that are protected by the **GPIOCR** register. Because of this, the register type for GPIO Port B7 and GPIO Port C[3:0] is R/W.

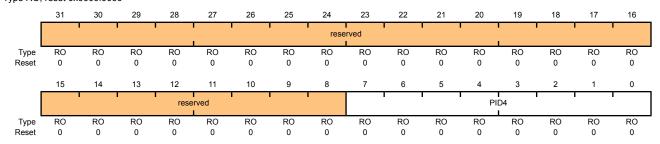

The default reset value for the **GPIOCR** register is 0x0000.00FF for all GPIO pins, with the exception of the five JTAG/SWD pins (PB7 and PC[3:0]). To ensure that the JTAG port is not accidentally programmed as a GPIO, these five pins default to non-commitable. Because of this, the default reset value of **GPIOCR** for GPIO Port B is 0x0000.007F while the default reset value of **GPIOCR** for Port C is 0x0000.00FO.

Register 21: GPIO Peripheral Identification 4 (GPIOPeriphID4), offset 0xFD0

The **GPIOPeriphID4**, **GPIOPeriphID5**, **GPIOPeriphID6**, and **GPIOPeriphID7** registers can conceptually be treated as one 32-bit register; each register contains eight bits of the 32-bit register, used by software to identify the peripheral.

9 General-Purpose Timers

Programmable timers can be used to count or time external events that drive the Timer input pins. The Stellaris® General-Purpose Timer Module (GPTM) contains three GPTM blocks (Timer0, Timer1, and Timer 2). Each GPTM block provides two 16-bit timers/counters (referred to as TimerA and TimerB) that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions. The trigger signals from all of the general-purpose timers are ORed together before reaching the ADC module, so only one timer should be used to trigger ADC events.

Note: Timer2 is an internal timer and can only be used to generate internal interrupts or trigger ADC events.

The General-Purpose Timer Module is one timing resource available on the Stellaris[®] microcontrollers. Other timer resources include the System Timer (SysTick) (see "System Timer (SysTick)" on page 38) and the PWM timer in the PWM module (see "PWM Timer" on page 435).

The following modes are supported:

- 32-bit Timer modes
 - Programmable one-shot timer
 - Programmable periodic timer
 - Real-Time Clock using 32.768-KHz input clock
 - Software-controlled event stalling (excluding RTC mode)
- 16-bit Timer modes
 - General-purpose timer function with an 8-bit prescaler (for one-shot and periodic modes only)
 - Programmable one-shot timer
 - Programmable periodic timer
 - Software-controlled event stalling
- 16-bit Input Capture modes
 - Input edge count capture
 - Input edge time capture
- 16-bit PWM mode
 - Simple PWM mode with software-programmable output inversion of the PWM signal

9.1 Block Diagram

Note: In Figure 9-1 on page 178, the specific CCP pins available depend on the Stellaris[®] device. See Table 9-1 on page 178 for the available CCPs.

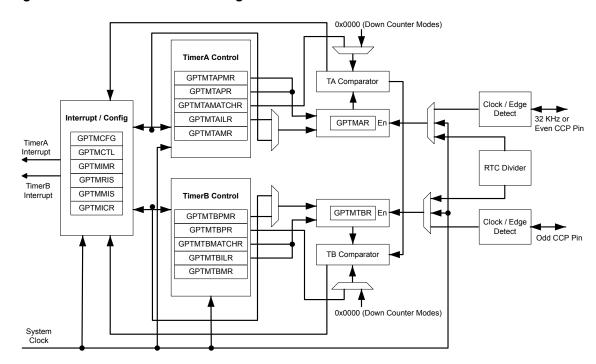

Figure 9-1. GPTM Module Block Diagram

Table 9-1. Available CCP Pins

Timer	16-Bit Up/Down Counter	Even CCP Pin	Odd CCP Pin
Timer 0	TimerA	CCP0	-
	TimerB	-	CCP1
Timer 1	TimerA	CCP2	-
	TimerB	-	CCP3
Timer 2	TimerA	-	-
	TimerB	-	-

9.2 Functional Description

The main components of each GPTM block are two free-running 16-bit up/down counters (referred to as TimerA and TimerB), two 16-bit match registers, two prescaler match registers, and two 16-bit load/initialization registers and their associated control functions. The exact functionality of each GPTM is controlled by software and configured through the register interface.

Software configures the GPTM using the **GPTM Configuration (GPTMCFG)** register (see page 189), the **GPTM TimerA Mode (GPTMTAMR)** register (see page 190), and the **GPTM TimerB Mode (GPTMTBMR)** register (see page 192). When in one of the 32-bit modes, the timer can only act as a 32-bit timer. However, when configured in 16-bit mode, the GPTM can have its two 16-bit timers configured in any combination of the 16-bit modes.

9.2.1 GPTM Reset Conditions

After reset has been applied to the GPTM module, the module is in an inactive state, and all control registers are cleared and in their default states. Counters TimerA and TimerB are initialized to 0xFFFF, along with their corresponding load registers: the **GPTM TimerA Interval Load**

(GPTMTAILR) register (see page 203) and the GPTM TimerB Interval Load (GPTMTBILR) register (see page 204). The prescale counters are initialized to 0x00: the GPTM TimerA Prescale (GPTMTAPR) register (see page 207) and the GPTM TimerB Prescale (GPTMTBPR) register (see page 208).

9.2.2 32-Bit Timer Operating Modes

This section describes the three GPTM 32-bit timer modes (One-Shot, Periodic, and RTC) and their configuration.

The GPTM is placed into 32-bit mode by writing a 0 (One-Shot/Periodic 32-bit timer mode) or a 1 (RTC mode) to the **GPTM Configuration (GPTMCFG)** register. In both configurations, certain GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- GPTM TimerA Interval Load (GPTMTAILR) register [15:0], see page 203
- GPTM TimerB Interval Load (GPTMTBILR) register [15:0], see page 204
- GPTM TimerA (GPTMTAR) register [15:0], see page 211
- GPTM TimerB (GPTMTBR) register [15:0], see page 212

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

```
GPTMTBILR[15:0]:GPTMTAILR[15:0]
```

Likewise, a read access to GPTMTAR returns the value:

GPTMTBR[15:0]:GPTMTAR[15:0]

9.2.2.1 32-Bit One-Shot/Periodic Timer Mode

In 32-bit one-shot and periodic timer modes, the concatenated versions of the TimerA and TimerB registers are configured as a 32-bit down-counter. The selection of one-shot or periodic mode is determined by the value written to the TAMR field of the **GPTM TimerA Mode (GPTMTAMR)** register (see page 190), and there is no need to write to the **GPTM TimerB Mode (GPTMTBMR)** register.

When software writes the TAEN bit in the **GPTM Control (GPTMCTL)** register (see page 194), the timer begins counting down from its preloaded value. Once the 0x0000.0000 state is reached, the timer reloads its start value from the concatenated **GPTMTAILR** on the next cycle. If configured to be a one-shot timer, the timer stops counting and clears the TAEN bit in the **GPTMCTL** register. If configured as a periodic timer, it continues counting.

In addition to reloading the count value, the GPTM generates interrupts and output triggers when it reaches the 0x0000000 state. The GPTM sets the TATORIS bit in the GPTM Raw Interrupt Status (GPTMRIS) register (see page 199), and holds it until it is cleared by writing the GPTM Interrupt Clear (GPTMICR) register (see page 201). If the time-out interrupt is enabled in the GPTM Interrupt Mask (GPTIMR) register (see page 197), the GPTM also sets the TATOMIS bit in the GPTM Masked Interrupt Status (GPTMMIS) register (see page 200).

The output trigger is a one-clock-cycle pulse that is asserted when the counter hits the 0x0000.0000 state, and deasserted on the following clock cycle. It is enabled by setting the TAOTE bit in **GPTMCTL**, and can trigger SoC-level events such as ADC conversions.

If software reloads the **GPTMTAILR** register while the counter is running, the counter loads the new value on the next clock cycle and continues counting from the new value.

If the TASTALL bit in the **GPTMCTL** register is asserted, the timer freezes counting until the signal is deasserted.

9.2.2.2 32-Bit Real-Time Clock Timer Mode

In Real-Time Clock (RTC) mode, the concatenated versions of the TimerA and TimerB registers are configured as a 32-bit up-counter. When RTC mode is selected for the first time, the counter is loaded with a value of 0x0000.0001. All subsequent load values must be written to the **GPTM TimerA Match (GPTMTAMATCHR)** register (see page 205) by the controller.

The input clock on the CCP0, CCP2, or CCP4 pins is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1 Hz rate and is passed along to the input of the 32-bit counter.

When software writes the TAEN bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x0000.0001. When the current count value matches the preloaded value in the **GPTMTAMATCHR** register, it rolls over to a value of 0x0000.0000 and continues counting until either a hardware reset, or it is disabled by software (clearing the TAEN bit). When a match occurs, the GPTM asserts the RTCRIS bit in **GPTMRIS**. If the RTC interrupt is enabled in **GPTIMR**, the GPTM also sets the RTCMIS bit in **GPTMISR** and generates a controller interrupt. The status flags are cleared by writing the RTCCINT bit in **GPTMICR**.

If the TASTALL and/or TBSTALL bits in the **GPTMCTL** register are set, the timer does not freeze if the RTCEN bit is set in **GPTMCTL**.

9.2.3 16-Bit Timer Operating Modes

The GPTM is placed into global 16-bit mode by writing a value of 0x4 to the **GPTM Configuration (GPTMCFG)** register (see page 189). This section describes each of the GPTM 16-bit modes of operation. TimerA and TimerB have identical modes, so a single description is given using an *n* to reference both.

9.2.3.1 16-Bit One-Shot/Periodic Timer Mode

In 16-bit one-shot and periodic timer modes, the timer is configured as a 16-bit down-counter with an optional 8-bit prescaler that effectively extends the counting range of the timer to 24 bits. The selection of one-shot or periodic mode is determined by the value written to the TnMR field of the **GPTMTnMR** register. The optional prescaler is loaded into the **GPTM Timern Prescale (GPTMTnPR)** register.

When software writes the \mathtt{TnEN} bit in the **GPTMCTL** register, the timer begins counting down from its preloaded value. Once the 0x0000 state is reached, the timer reloads its start value from **GPTMTnILR** and **GPTMTnPR** on the next cycle. If configured to be a one-shot timer, the timer stops counting and clears the \mathtt{TnEN} bit in the **GPTMCTL** register. If configured as a periodic timer, it continues counting.

In addition to reloading the count value, the timer generates interrupts and output triggers when it reaches the 0x0000 state. The GPTM sets the TnTORIS bit in the **GPTMRIS** register, and holds it until it is cleared by writing the **GPTMICR** register. If the time-out interrupt is enabled in **GPTIMR**, the GPTM also sets the TnTOMIS bit in **GPTMISR** and generates a controller interrupt.

The output trigger is a one-clock-cycle pulse that is asserted when the counter hits the 0x0000 state, and deasserted on the following clock cycle. It is enabled by setting the TnOTE bit in the **GPTMCTL** register, and can trigger SoC-level events such as ADC conversions.

If software reloads the **GPTMTAILR** register while the counter is running, the counter loads the new value on the next clock cycle and continues counting from the new value.

If the TnSTALL bit in the **GPTMCTL** register is enabled, the timer freezes counting until the signal is deasserted.

The following example shows a variety of configurations for a 16-bit free running timer while using the prescaler. All values assume a 50-MHz clock with Tc=20 ns (clock period).

Table 9-2. 16-Bit Timer With Prescaler Configurations

Prescale	#Clock (T c) ^a	Max Time	Units
00000000	1	1.3107	mS
00000001	2	2.6214	mS
00000010	3	3.9321	mS
11111100	254	332.9229	mS
11111110	255	334.2336	mS
11111111	256	335.5443	mS

a. Tc is the clock period.

9.2.3.2 16-Bit Input Edge Count Mode

In Edge Count mode, the timer is configured as a down-counter capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge Count mode, the TnCMR bit of the GPTMTnMR register must be set to 0. The type of edge that the timer counts is determined by the TnEVENT fields of the GPTMCTL register. During initialization, the GPTM Timern Match (GPTMTnMATCHR) register is configured so that the difference between the value in the GPTMTnILR register and the GPTMTnMATCHR register equals the number of edge events that must be counted.

When software writes the TnEN bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements the counter by 1 until the event count matches **GPTMTnMATCHR**. When the counts match, the GPTM asserts the CnMRIS bit in the **GPTMRIS** register (and the CnMMIS bit, if the interrupt is not masked). The counter is then reloaded using the value in **GPTMTnILR**, and stopped since the GPTM automatically clears the TnEN bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until TnEN is re-enabled by software.

Figure 9-2 on page 182 shows how input edge count mode works. In this case, the timer start value is set to **GPTMnILR** =0x000A and the match value is set to **GPTMnMATCHR** =0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted since the timer automatically clears the TnEN bit after the current count matches the value in the **GPTMnMR** register.

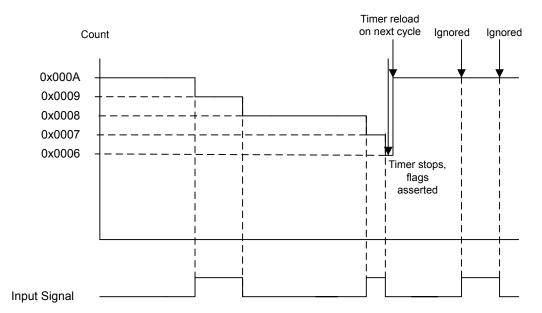

Figure 9-2. 16-Bit Input Edge Count Mode Example

9.2.3.3 16-Bit Input Edge Time Mode

Note: The prescaler is not available in 16-Bit Input Edge Time mode.

In Edge Time mode, the timer is configured as a free-running down-counter initialized to the value loaded in the **GPTMTnILR** register (or 0xFFFF at reset). This mode allows for event capture of both rising and falling edges. The timer is placed into Edge Time mode by setting the TnCMR bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the TnEVENT fields of the **GPTMCnTL** register.

When software writes the TnEN bit in the **GPTMCTL** register, the timer is enabled for event capture. When the selected input event is detected, the current **Tn** counter value is captured in the **GPTMTnR** register and is available to be read by the controller. The GPTM then asserts the CnERIS bit (and the CnEMIS bit, if the interrupt is not masked).

After an event has been captured, the timer does not stop counting. It continues to count until the ${\tt TnEN}$ bit is cleared. When the timer reaches the 0x0000 state, it is reloaded with the value from the **GPTMnILR** register.

Figure 9-3 on page 183 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the **GPTMTnR** register, and is held there until another rising edge is detected (at which point the new count value is loaded into **GPTMTnR**).

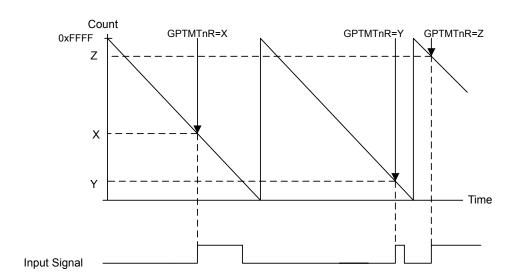

Figure 9-3. 16-Bit Input Edge Time Mode Example

9.2.3.4 16-Bit PWM Mode

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a down-counter with a start value (and thus period) defined by **GPTMTnILR**. PWM mode is enabled with the **GPTMTnMR** register by setting the TnAMS bit to 0x1, the TnCMR bit to 0x0, and the TnMR field to 0x2.

When software writes the TnEN bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0000 state. On the next counter cycle, the counter reloads its start value from **GPTMTnILR** (and **GPTMTnPR** if using a prescaler) and continues counting until disabled by software clearing the TnEN bit in the **GPTMCTL** register. No interrupts or status bits are asserted in PWM mode.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** register (its start state), and is deasserted when the counter value equals the value in the **GPTM Timern Match Register (GPTMnMATCHR)**. Software has the capability of inverting the output PWM signal by setting the TnPWML bit in the **GPTMCTL** register.

Figure 9-4 on page 184 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and **TnPWML** =0 (duty cycle would be 33% for the **TnPWML** =1 configuration). For this example, the start value is **GPTMnIRL**=0xC350 and the match value is **GPTMnMR**=0x411A.

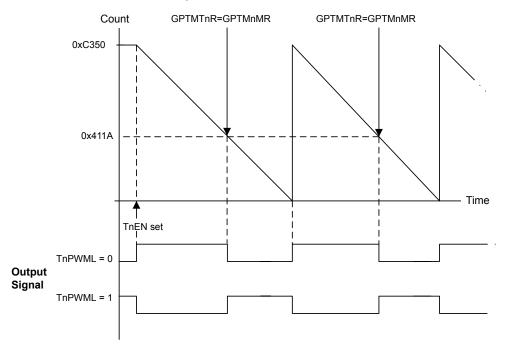

Figure 9-4. 16-Bit PWM Mode Example

9.3 Initialization and Configuration

To use the general-purpose timers, the peripheral clock must be enabled by setting the TIMERO, TIMER1, and TIMER2 bits in the **RCGC1** register.

This section shows module initialization and configuration examples for each of the supported timer modes.

9.3.1 32-Bit One-Shot/Periodic Timer Mode

The GPTM is configured for 32-bit One-Shot and Periodic modes by the following sequence:

- 1. Ensure the timer is disabled (the TAEN bit in the **GPTMCTL** register is cleared) before making any changes.
- 2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0.
- 3. Set the TAMR field in the GPTM TimerA Mode Register (GPTMTAMR):
 - a. Write a value of 0x1 for One-Shot mode.
 - b. Write a value of 0x2 for Periodic mode.
- 4. Load the start value into the GPTM TimerA Interval Load Register (GPTMTAILR).
- If interrupts are required, set the TATOIM bit in the GPTM Interrupt Mask Register (GPTMIMR).
- 6. Set the TAEN bit in the **GPTMCTL** register to enable the timer and start counting.

7. Poll the TATORIS bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the TATOCINT bit of the **GPTM** Interrupt Clear Register (GPTMICR).

In One-Shot mode, the timer stops counting after step 7 on page 185. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode does not stop counting after it times out.

9.3.2 32-Bit Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on its CCP0, CCP2, or CCP4 pins. To enable the RTC feature, follow these steps:

- 1. Ensure the timer is disabled (the TAEN bit is cleared) before making any changes.
- 2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x1.
- Write the desired match value to the GPTM TimerA Match Register (GPTMTAMATCHR).
- Set/clear the RTCEN bit in the GPTM Control Register (GPTMCTL) as desired.
- If interrupts are required, set the RTCIM bit in the GPTM Interrupt Mask Register (GPTMIMR).
- 6. Set the TAEN bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTAMATCHR** register, the counter is re-loaded with 0x0000.0000 and begins counting. If an interrupt is enabled, it does not have to be cleared.

9.3.3 16-Bit One-Shot/Periodic Timer Mode

A timer is configured for 16-bit One-Shot and Periodic modes by the following sequence:

- Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
- 2. Write the GPTM Configuration Register (GPTMCFG) with a value of 0x4.
- 3. Set the TnMR field in the **GPTM Timer Mode (GPTMTnMR)** register:
 - a. Write a value of 0x1 for One-Shot mode.
 - b. Write a value of 0x2 for Periodic mode.
- If a prescaler is to be used, write the prescale value to the GPTM Timern Prescale Register (GPTMTnPR).
- Load the start value into the GPTM Timer Interval Load Register (GPTMTnILR).
- If interrupts are required, set the Thtolm bit in the GPTM Interrupt Mask Register (GPTMIMR).
- Set the TnEN bit in the GPTM Control Register (GPTMCTL) to enable the timer and start counting.
- 8. Poll the TnTORIS bit in the GPTMRIS register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the TnTOCINT bit of the GPTM Interrupt Clear Register (GPTMICR).

In One-Shot mode, the timer stops counting after step 8 on page 185. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode does not stop counting after it times out.

9.3.4 16-Bit Input Edge Count Mode

A timer is configured to Input Edge Count mode by the following sequence:

- 1. Ensure the timer is disabled (the THEN bit is cleared) before making any changes.
- 2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
- 3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the TnCMR field to 0x0 and the TnMR field to 0x3.
- Configure the type of event(s) that the timer captures by writing the Tnevent field of the GPTM Control (GPTMCTL) register.
- Load the timer start value into the GPTM Timern Interval Load (GPTMTnILR) register.
- Load the desired event count into the GPTM Timern Match (GPTMTnMATCHR) register.
- 7. If interrupts are required, set the CnMIM bit in the GPTM Interrupt Mask (GPTMIMR) register.
- 8. Set the TnEN bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
- 9. Poll the CnMRIS bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the CnMCINT bit of the **GPTM** Interrupt Clear (GPTMICR) register.

In Input Edge Count Mode, the timer stops after the desired number of edge events has been detected. To re-enable the timer, ensure that the TnEN bit is cleared and repeat step 4 on page 186 through step 9 on page 186.

9.3.5 16-Bit Input Edge Timing Mode

A timer is configured to Input Edge Timing mode by the following sequence:

- 1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
- 2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
- In the GPTM Timer Mode (GPTMTnMR) register, write the TnCMR field to 0x1 and the TnMR field to 0x3.
- 4. Configure the type of event that the timer captures by writing the Tnevent field of the **GPTM** Control (GPTMCTL) register.
- 5. Load the timer start value into the GPTM Timern Interval Load (GPTMTnILR) register.
- 6. If interrupts are required, set the Cneim bit in the GPTM Interrupt Mask (GPTMIMR) register.
- Set the Then bit in the GPTM Control (GPTMCTL) register to enable the timer and start counting.
- 8. Poll the Cners bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the Cnecint bit of the **GPTM**

Interrupt Clear (GPTMICR) register. The time at which the event happened can be obtained by reading the **GPTM Timern (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register. The change takes effect at the next cycle after the write.

9.3.6 16-Bit PWM Mode

A timer is configured to PWM mode using the following sequence:

- 1. Ensure the timer is disabled (the TnEN bit is cleared) before making any changes.
- 2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
- 3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the TnAMS bit to 0x1, the TnCMR bit to 0x0, and the TnMR field to 0x2.
- 4. Configure the output state of the PWM signal (whether or not it is inverted) in the TREVENT field of the GPTM Control (GPTMCTL) register.
- Load the timer start value into the GPTM Timern Interval Load (GPTMTnILR) register.
- 6. Load the GPTM Timern Match (GPTMTnMATCHR) register with the desired value.
- If a prescaler is going to be used, configure the GPTM Timern Prescale (GPTMTnPR) register and the GPTM Timern Prescale Match (GPTMTnPMR) register.
- 8. Set the TnEN bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Timing mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

9.4 Register Map

Table 9-3 on page 187 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

Timer0: 0x4003.0000

Timer1: 0x4003.1000

Timer2: 0x4003.2000

Table 9-3. Timers Register Map

Offset	Name	Type	Reset	Description	See page

9.5 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

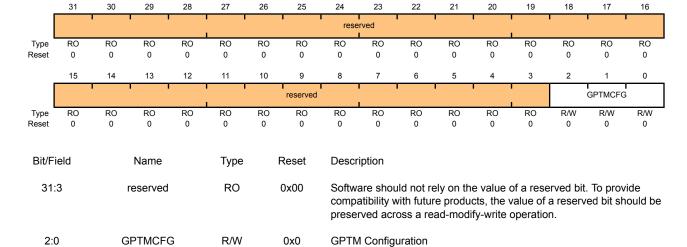

Register 1: GPTM Configuration (GPTMCFG), offset 0x000

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 16-bit mode.

GPTM Configuration (GPTMCFG)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000 Offset 0x000

Type R/W, reset 0x0000.0000

The GPTMCFG values are defined as follows:

Value Description

0x0 32-bit timer configuration.

0x1 32-bit real-time clock (RTC) counter configuration.

0x2 Reserved.0x3 Reserved.

0x4-0x7 16-bit timer configuration, function is controlled by bits 1:0 of **GPTMTAMR** and **GPTMTBMR**.

Register 2: GPTM TimerA Mode (GPTMTAMR), offset 0x004

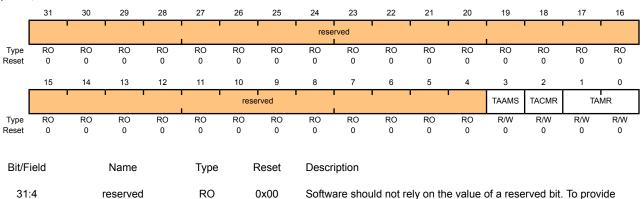

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in 16-bit PWM mode, set the TAAMS bit to 0x1, the TACMR bit to 0x0, and the TAMR field to 0x2.

GPTM TimerA Mode (GPTMTAMR)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000

Offset 0x004

Type R/W, reset 0x0000.0000

3 TAAMS R/W 0

compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

The TAAMS values are defined as follows:

GPTM TimerA Alternate Mode Select

Value Description

Capture mode is enabled.

1 PWM mode is enabled.

Note: To enable PWM mode, you must also clear the TACMR bit and set the TAMR field to 0x2.

2 TACMR

R/W

GPTM TimerA Capture Mode

The TACMR values are defined as follows:

Value Description

- D Edge-Count mode.
- Edge-Time mode.

In 32-bit timer configuration, this register controls the mode and the contents of $\ensuremath{\mathbf{GPTMTBMR}}$ are ignored.

Bit/Field	Name	Туре	Reset	Description
1:0	TAMR	R/W	0x0	GPTM TimerA Mode
				The TAMR values are defined as follows:
				Value Description
				0x0 Reserved.
				0x1 One-Shot Timer mode.
				0x2 Periodic Timer mode.
				0x3 Capture mode.
				The Timer mode is based on the timer configuration defined by bits 2:0 in the GPTMCFG register (16-or 32-bit).
				In 16-bit timer configuration, ${\tt TAMR}$ controls the 16-bit timer modes for TimerA.

Register 3: GPTM TimerB Mode (GPTMTBMR), offset 0x008

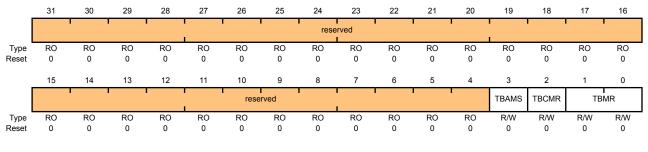

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in 16-bit PWM mode, set the TBAMS bit to 0x1, the TBCMR bit to 0x0, and the TBMR field to 0x2.

GPTM TimerB Mode (GPTMTBMR)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000

Offset 0x008

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TBAMS	R/W	0	GPTM TimerB Alternate Mode Select

GPTM TimerB Alternate Mode Select

The TBAMS values are defined as follows:

Value Description

Capture mode is enabled.

PWM mode is enabled.

To enable PWM mode, you must also clear the TBCMR Note: bit and set the TBMR field to 0x2.

2 **TBCMR** R/W **GPTM TimerB Capture Mode**

The TBCMR values are defined as follows:

Value Description

Edge-Count mode.

Edge-Time mode.

1:0	TBMR	R/W	0x0	GPTM TimerB Mode	
				The TBMR values are defined as follows:	
				Value Description	
				0x0 Reserved.	
				0x1 One-Shot Timer mode.	

Description

Reset

Bit/Field

Name

Type

0x2 Periodic Timer mode.

0x3 Capture mode.

The timer mode is based on the timer configuration defined by bits 2:0 in the $\mbox{\bf GPTMCFG}$ register.

In 16-bit timer configuration, these bits control the 16-bit timer modes for $\mathsf{TimerB}.$

In 32-bit timer configuration, this register's contents are ignored and $\ensuremath{\mathbf{GPTMTAMR}}$ is used.

Register 4: GPTM Control (GPTMCTL), offset 0x00C

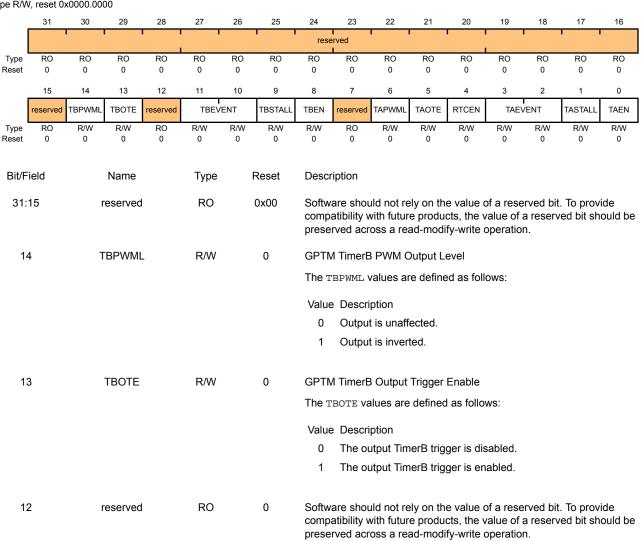

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

GPTM Control (GPTMCTL)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000

Offset 0x00C

Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
11:10	TBEVENT	R/W	0x0	GPTM TimerB Event Mode
				The TBEVENT values are defined as follows:
				Value Description
				0x0 Positive edge.
				0x1 Negative edge.
				0x2 Reserved
				0x3 Both edges.
9	TBSTALL	R/W	0	GPTM TimerB Stall Enable
				The TBSTALL values are defined as follows:
				Value Description
				0 TimerB stalling is disabled.
				1 TimerB stalling is enabled.
8	TBEN	R/W	0	GPTM TimerB Enable
				The TBEN values are defined as follows:
				Value Description
				0 TimerB is disabled.
				1 TimerB is enabled and begins counting or the capture logic is enabled based on the GPTMCFG register.
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	TAPWML	R/W	0	GPTM TimerA PWM Output Level
				The TAPWML values are defined as follows:
				Value Description
				0 Output is unaffected.
				1 Output is inverted.
5	TAOTE	R/W	0	GPTM TimerA Output Trigger Enable
				The TAOTE values are defined as follows:
				Value Description
				0 The output TimerA trigger is disabled.
				1 The output TimerA trigger is enabled.

Bit/Field	Name	Type	Reset	Description
4	RTCEN	R/W	0	GPTM RTC Enable
				The RTCEN values are defined as follows:
				Value Description
				0 RTC counting is disabled.
				1 RTC counting is enabled.
3:2	TAEVENT	R/W	0x0	GPTM TimerA Event Mode
				The TAEVENT values are defined as follows:
				Value Description
				0x0 Positive edge.
				0x1 Negative edge.
				0x2 Reserved
				0x3 Both edges.
1	TASTALL	R/W	0	GPTM TimerA Stall Enable
				The TASTALL values are defined as follows:
				Value Description
				0 TimerA stalling is disabled.
				1 TimerA stalling is enabled.
0	TAEN	R/W	0	GPTM TimerA Enable
				The TAEN values are defined as follows:
				Value Description
				0 TimerA is disabled.

- TimerA is enabled and begins counting or the capture logic is enabled based on the **GPTMCFG** register.

Register 5: GPTM Interrupt Mask (GPTMIMR), offset 0x018

This register allows software to enable/disable GPTM controller-level interrupts. Writing a 1 enables the interrupt, while writing a 0 disables it.

GPTM Interrupt Mask (GPTMIMR)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000 Offset 0x018 Type R/W, reset 0x0000.0000

Register 6: GPTM Raw Interrupt Status (GPTMRIS), offset 0x01C

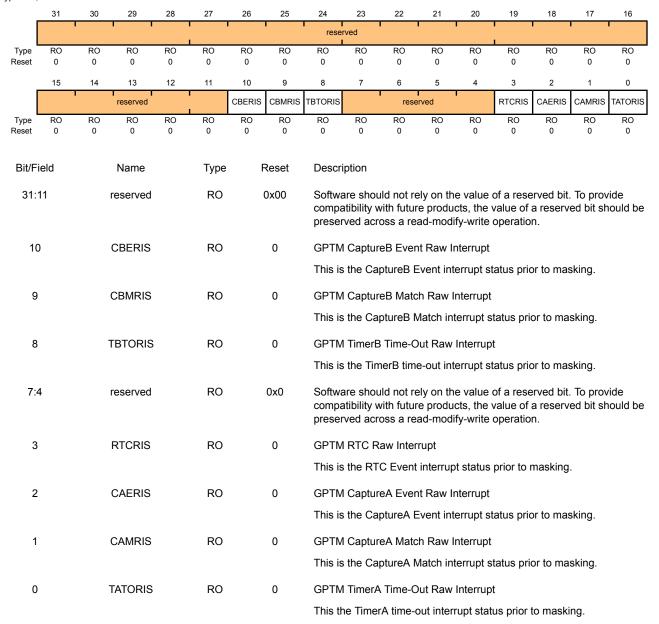

This register shows the state of the GPTM's internal interrupt signal. These bits are set whether or not the interrupt is masked in the **GPTMIMR** register. Each bit can be cleared by writing a 1 to its corresponding bit in **GPTMICR**.

GPTM Raw Interrupt Status (GPTMRIS)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000

Offset 0x01C

Type RO, reset 0x0000.0000

Register 7: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

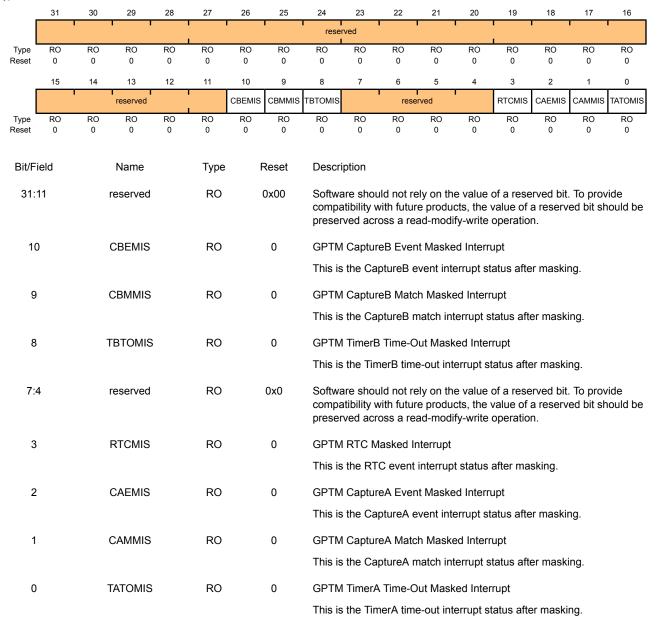

This register show the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

GPTM Masked Interrupt Status (GPTMMIS)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000

The interrupt is cleared.

Register 9: GPTM TimerA Interval Load (GPTMTAILR), offset 0x028

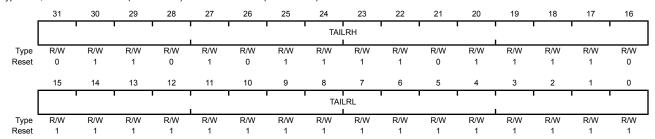

This register is used to load the starting count value into the timer. When GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM TimerB Interval Load (GPTMTBILR)** register). In 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

GPTM TimerA Interval Load (GPTMTAILR)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000

Offset 0x028

Type R/W, reset 0x0000.FFFF (16-bit mode) and 0xFFFF.FFFF (32-bit mode)

Bit/Field	Name	Туре	Reset	Description
31:16	TAILRH	R/W	0xFFFF (32-bit mode) 0x0000 (16-bit mode)	GPTM TimerA Interval Load Register High When configured for 32-bit mode via the GPTMCFG register, the GPTM TimerB Interval Load (GPTMTBILR) register loads this value on a write. A read returns the current value of GPTMTBILR.
				In 16-bit mode, this field reads as 0 and does not have an effect on the state of $\ensuremath{\mathbf{GPTMTBILR}}.$
15:0	TAILRL	R/W	0xFFFF	GPTM TimerA Interval Load Register Low

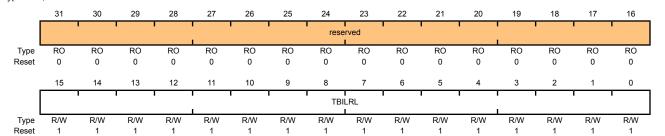

For both 16- and 32-bit modes, writing this field loads the counter for TimerA. A read returns the current value of **GPTMTAILR**.

Register 10: GPTM TimerB Interval Load (GPTMTBILR), offset 0x02C

This register is used to load the starting count value into TimerB. When the GPTM is configured to a 32-bit mode, **GPTMTBILR** returns the current value of TimerB and ignores writes.

GPTM TimerB Interval Load (GPTMTBILR)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000 Offset 0x02C Type R/W, reset 0x0000.FFFF

Bit/Field	Name	Туре	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TBILRL	R/W	0xFFFF	GPTM TimerB Interval Load Register

When the GPTM is not configured as a 32-bit timer, a write to this field updates **GPTMTBILR**. In 32-bit mode, writes are ignored, and reads return the current value of **GPTMTBILR**.

Register 11: GPTM TimerA Match (GPTMTAMATCHR), offset 0x030

This register is used in 32-bit Real-Time Clock mode and 16-bit PWM and Input Edge Count modes.

GPTM TimerA Match (GPTMTAMATCHR)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000

Offset 0x030

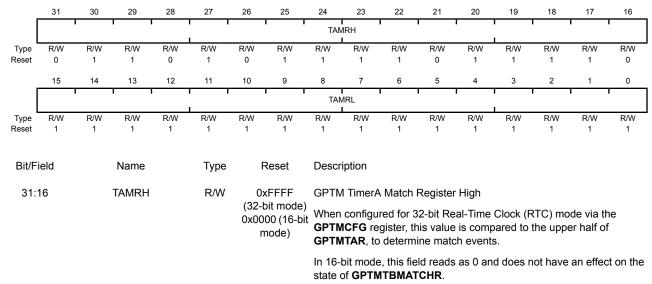

15:0

Type R/W, reset 0x0000.FFFF (16-bit mode) and 0xFFFF.FFFF (32-bit mode)

TAMRL

R/W

0xFFFF

When configured for 32-bit Real-Time Clock (RTC) mode via the **GPTMCFG** register, this value is compared to the lower half of **GPTMTAR**, to determine match events.

GPTM TimerA Match Register Low

When configured for PWM mode, this value along with **GPTMTAILR**, determines the duty cycle of the output PWM signal.

When configured for Edge Count mode, this value along with **GPTMTAILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTAILR** minus this value.

Register 12: GPTM TimerB Match (GPTMTBMATCHR), offset 0x034

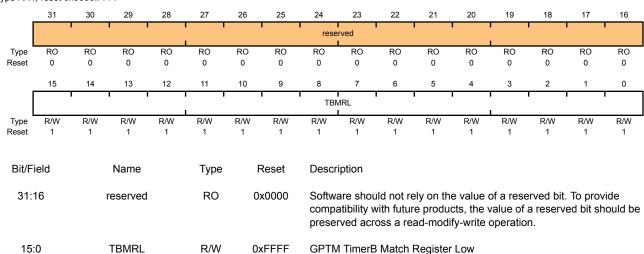

This register is used in 32-bit Real-Time Clock mode and 16-bit PWM and Input Edge Count modes.

GPTM TimerB Match (GPTMTBMATCHR)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000

Offset 0x034

Type R/W, reset 0x0000.FFFF

When configured for PWM mode, this value along with **GPTMTBILR**, determines the duty cycle of the output PWM signal.

When configured for Edge Count mode, this value along with **GPTMTBILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTBILR** minus this value.

Register 13: GPTM TimerA Prescale (GPTMTAPR), offset 0x038

This register allows software to extend the range of the 16-bit timers when operating in one-shot or periodic mode.

GPTM TimerA Prescale (GPTMTAPR)

TAPSR

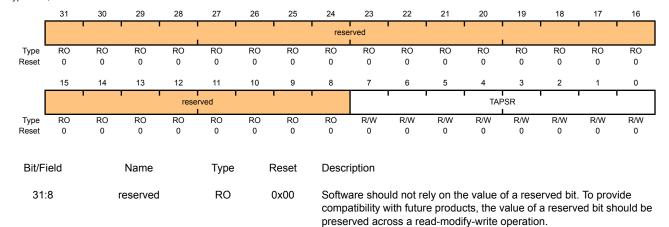

R/W

0x00

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000 Offset 0x038

Type R/W, reset 0x0000.0000

7:0

GPTM TimerA Prescale

The register loads this value on a write. A read returns the current value of the register.

Refer to Table 9-2 on page 181 for more details and an example.

Register 14: GPTM TimerB Prescale (GPTMTBPR), offset 0x03C

This register allows software to extend the range of the 16-bit timers when operating in one-shot or periodic mode.

GPTM TimerB Prescale (GPTMTBPR)

TBPSR

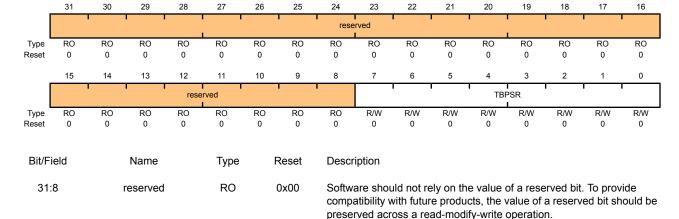

R/W

0x00

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000 Offset 0x03C

7:0

GPTM TimerB Prescale

The register loads this value on a write. A read returns the current value of this register.

Refer to Table 9-2 on page 181 for more details and an example.

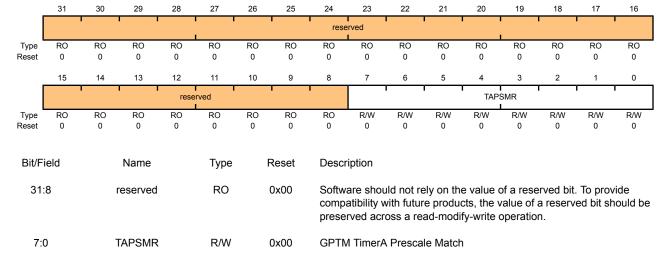

Register 15: GPTM TimerA Prescale Match (GPTMTAPMR), offset 0x040

This register effectively extends the range of **GPTMTAMATCHR** to 24 bits when operating in 16-bit one-shot or periodic mode.

GPTM TimerA Prescale Match (GPTMTAPMR)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000 Offset 0x040

Type R/W, reset 0x0000.0000

This value is used alongside **GPTMTAMATCHR** to detect timer match events while using a prescaler.

Register 16: GPTM TimerB Prescale Match (GPTMTBPMR), offset 0x044

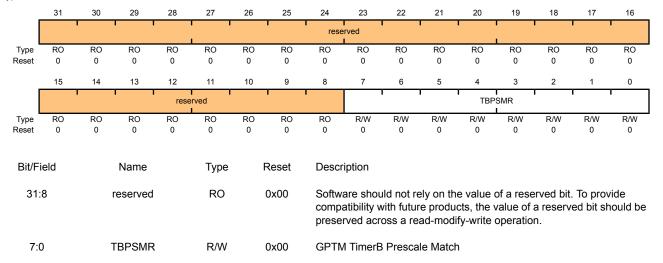

This register effectively extends the range of GPTMTBMATCHR to 24 bits when operating in 16-bit one-shot or periodic mode.

GPTM TimerB Prescale Match (GPTMTBPMR)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000

Offset 0x044

Type R/W, reset 0x0000.0000

This value is used alongside **GPTMTBMATCHR** to detect timer match events while using a prescaler.

Register 17: GPTM TimerA (GPTMTAR), offset 0x048

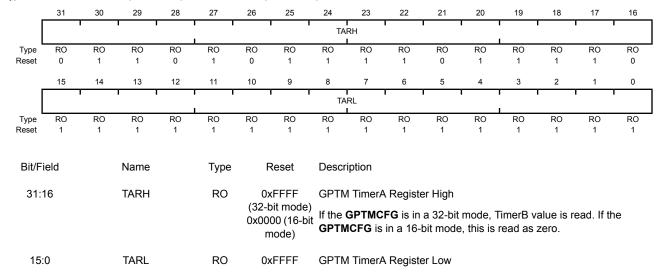

This register shows the current value of the TimerA counter in all cases except for Input Edge Count mode. When in this mode, this register contains the time at which the last edge event took place.

GPTM TimerA (GPTMTAR)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000

Offset 0x048

Type RO, reset 0x0000.FFFF (16-bit mode) and 0xFFFF.FFFF (32-bit mode)

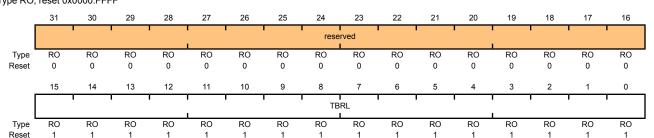

A read returns the current value of the **GPTM TimerA Count Register**, except in Input Edge Count mode, when it returns the timestamp from the last edge event.

Register 18: GPTM TimerB (GPTMTBR), offset 0x04C

This register shows the current value of the TimerB counter in all cases except for Input Edge Count mode. When in this mode, this register contains the time at which the last edge event took place.

GPTM TimerB (GPTMTBR)

Timer0 base: 0x4003.0000 Timer1 base: 0x4003.1000 Timer2 base: 0x4003.2000 Offset 0x04C Type RO, reset 0x0000.FFFF

Bit/Field	Name	Type	Reset	Description
Divi ielu	Name	Type	Nesei	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TBRL	RO	0xFFFF	GPTM TimerB

A read returns the current value of the **GPTM TimerB Count Register**, except in Input Edge Count mode, when it returns the timestamp from the last edge event.

10 Watchdog Timer

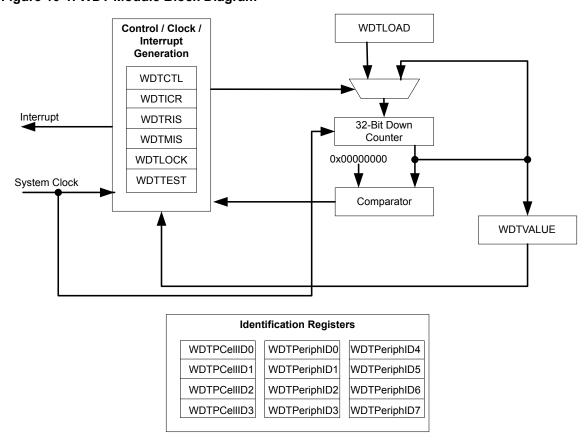

A watchdog timer can generate nonmaskable interrupts (NMIs) or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way.

The Stellaris[®] Watchdog Timer module consists of a 32-bit down counter, a programmable load register, interrupt generation logic, a locking register, and user-enabled stalling.

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

10.1 Block Diagram

Figure 10-1. WDT Module Block Diagram

10.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the

Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled (via the WatchdogResetEnable function), the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

10.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the WDT bit in the **RCGC0** register. The Watchdog Timer is configured using the following sequence:

- 1. Load the **WDTLOAD** register with the desired timer load value.
- If the Watchdog is configured to trigger system resets, set the RESEN bit in the WDTCTL register.
- Set the INTEN bit in the WDTCTL register to enable the Watchdog and lock the control register.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of 0x1ACC.E551.

10.4 Register Map

Table 10-1 on page 214 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address of 0x4000.0000.

Table 10-1. Watchdog Timer Register Map

10.5 Register Descriptions

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

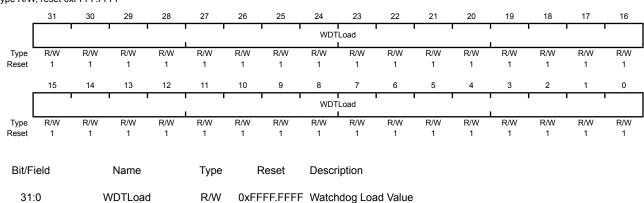

Register 1: Watchdog Load (WDTLOAD), offset 0x000

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

Watchdog Load (WDTLOAD)

Base 0x4000.0000

Offset 0x000 Type R/W, reset 0xFFFF.FFF

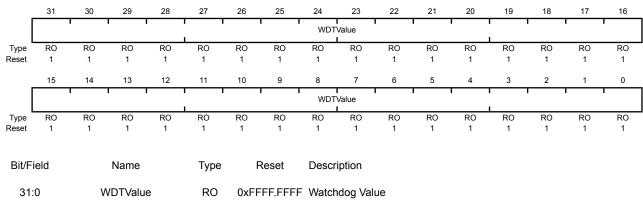

Register 2: Watchdog Value (WDTVALUE), offset 0x004

This register contains the current count value of the timer.

Watchdog Value (WDTVALUE)

Base 0x4000.0000

Offset 0x004
Type RO, reset 0xFFFF.FFF

Current value of the 32-bit down counter.

Register 3: Watchdog Control (WDTCTL), offset 0x008

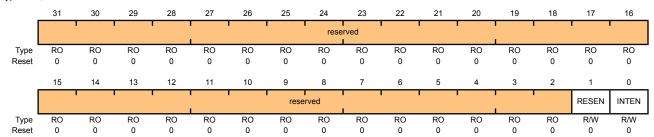

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled, all subsequent writes to the control register are ignored. The only mechanism that can re-enable writes is a hardware reset.

Watchdog Control (WDTCTL)

Base 0x4000.0000 Offset 0x008

Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	RESEN	R/W	0	Watchdog Reset Enable The RESEN values are defined as follows: Value Description 0 Disabled. 1 Enable the Watchdog module reset output.
0	INTEN	R/W	0	Watchdog Interrupt Enable

The INTEN values are defined as follows:

Value Description

- 0 Interrupt event disabled (once this bit is set, it can only be cleared by a hardware reset).
- 1 Interrupt event enabled. Once enabled, all writes are ignored.

Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Value for a read or reset is indeterminate.

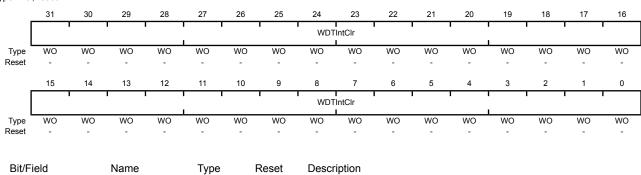

Watchdog Interrupt Clear (WDTICR)

WDTIntClr

WO

Base 0x4000.0000 Offset 0x00C Type WO, reset -

31:0

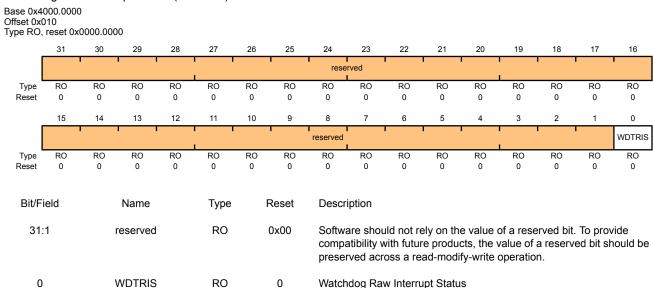

Watchdog Interrupt Clear

Register 5: Watchdog Raw Interrupt Status (WDTRIS), offset 0x010

This register is the raw interrupt status register. Watchdog interrupt events can be monitored via this register if the controller interrupt is masked.

Watchdog Raw Interrupt Status (WDTRIS)

Gives the raw interrupt state (prior to masking) of WDTINTR.

Register 6: Watchdog Masked Interrupt Status (WDTMIS), offset 0x014

This register is the masked interrupt status register. The value of this register is the logical AND of the raw interrupt bit and the Watchdog interrupt enable bit.

Watchdog Masked Interrupt Status (WDTMIS)

WDTMIS

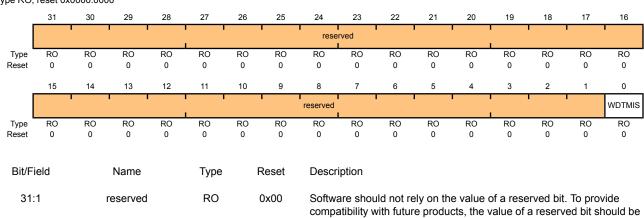

RO

0

Base 0x4000.0000

0

Offset 0x014
Type RO, reset 0x0000.0000

Gives the masked interrupt state (after masking) of the $\mbox{\bf WDTINTR}$ interrupt.

preserved across a read-modify-write operation.

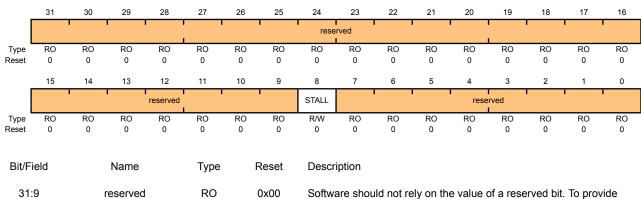

Watchdog Masked Interrupt Status

Register 7: Watchdog Test (WDTTEST), offset 0x418

This register provides user-enabled stalling when the microcontroller asserts the CPU halt flag during debug.

Watchdog Test (WDTTEST)

Base 0x4000.0000 Offset 0x418 Type R/W, reset 0x0000.0000

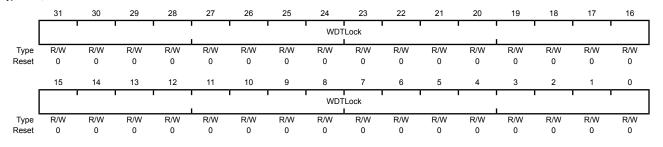

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	STALL	R/W	0	Watchdog Stall Enable
				When set to 1, if the Stellaris [®] microcontroller is stopped with a debugger, the watchdog timer stops counting. Once the microcontroller is restarted, the watchdog timer resumes counting.
7:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide

Register 8: Watchdog Lock (WDTLOCK), offset 0xC00

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

Watchdog Lock (WDTLOCK)

Base 0x4000.0000 Offset 0xC00 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	WDTLock	R/W	0x0000	Watchdog Lock

A write of the value 0x1ACC.E551 unlocks the watchdog registers for write access. A write of any other value reapplies the lock, preventing any register updates.

A read of this register returns the following values:

Value Description
0x0000.0001 Locked
0x0000.0000 Unlocked

Register 9: Watchdog Peripheral Identification 4 (WDTPeriphID4), offset 0xFD0

The WDTPeriphIDn registers are hard-coded and the fields within the register determine the reset value.

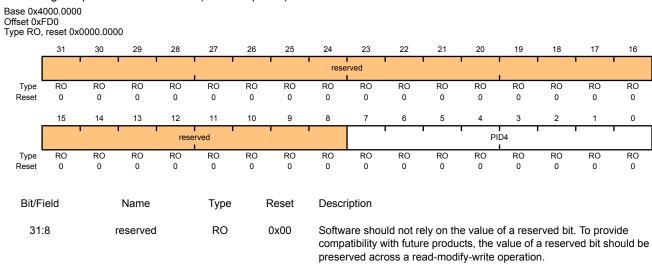

Watchdog Peripheral Identification 4 (WDTPeriphID4)

PID4

RO

0x00

7:0

11 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number.

The Stellaris[®] ADC module features 10-bit conversion resolution and supports three input channels, plus an internal temperature sensor. The ADC module contains a programmable sequencer which allows for the sampling of multiple analog input sources without controller intervention. Each sample sequence provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequence priority.

The Stellaris® ADC provides the following features:

- Three analog input channels
- Single-ended and differential-input configurations
- Internal temperature sensor
- Sample rate of 250 thousand samples/second
- Four programmable sample conversion sequences from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
 - Controller (software)
 - Timers
 - Analog Comparators
 - PWM
 - GPIO
- Hardware averaging of up to 64 samples for improved accuracy

Figure 11-1. ADC Module Block Diagram

11.2 Functional Description

SS2 Interrupt

The Stellaris[®] ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approach found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the controller. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence.

11.2.1 Sample Sequencers

The sampling control and data capture is handled by the Sample Sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 11-1 on page 237 shows the maximum number of samples that each Sequencer can capture and its corresponding FIFO depth. In this implementation, each FIFO entry is a 32-bit word, with the lower 10 bits containing the conversion result.

Table 11-1. Samples and FIFO Depth of Sequencers

ADCISC

Sequencer	Number of Samples	Depth of FIFO
SS3	1	1
SS2	4	4
SS1	4	4
SS0	8	8

For a given sample sequence, each sample is defined by two 4-bit nibbles in the ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn) and ADC Sample Sequence Control (ADCSSCTLn) registers, where "n" corresponds to the sequence number. The ADCSSMUXn nibbles select the input pin, while the ADCSSCTLn nibbles contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample Sequencers are enabled by setting the respective ASENn bit in the ADC Active Sample Sequencer (ADCACTSS) register, but can be configured before being enabled.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence is allowed. In the ADCSSCTLn register, the Interrupt Enable (IE) bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the END bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the END bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO** (**ADCSSFIFOn**) registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status** (**ADCSSFSTATn**) registers along with FULL and EMPTY status flags. Overflow and underflow conditions are monitored using the **ADCOSTAT** and **ADCUSTAT** registers.

11.2.2 Module Control

Outside of the Sample Sequencers, the remainder of the control logic is responsible for tasks such as interrupt generation, sequence prioritization, and trigger configuration.

Most of the ADC control logic runs at the ADC clock rate of 14-18 MHz. The internal ADC divider is configured automatically by hardware when the system XTAL is selected. The automatic clock divider configuration targets 16.667 MHz operation for all Stellaris[®] devices.

11.2.2.1 Interrupts

The Sample Sequencers dictate the events that cause interrupts, but they don't have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signal is controlled by the state of the MASK bits in the ADC Interrupt Mask (ADCIM) register. Interrupt status can be viewed at two locations: the ADC Raw Interrupt Status (ADCRIS) register, which shows the raw status of a Sample Sequencer's interrupt signal, and the ADC Interrupt Status and Clear (ADCISC) register, which shows the logical AND of the ADCRIS register's INR bit and the ADCIM register's MASK bits. Interrupts are cleared by writing a 1 to the corresponding IN bit in ADCISC.

11.2.2.2 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active Sample Sequencer units with the same priority do not provide consistent results, so software must ensure that all active Sample Sequencer units have a unique priority value.

11.2.2.3 Sampling Events

Sample triggering for each Sample Sequencer is defined in the **ADC Event Multiplexer Select** (**ADCEMUX**) register. The external peripheral triggering sources vary by Stellaris[®] family member,

but all devices share the "Controller" and "Always" triggers. Software can initiate sampling by setting the CH bits in the ADC Processor Sample Sequence Initiate (ADCPSSI) register.

When using the "Always" trigger, care must be taken. If a sequence's priority is too high, it is possible to starve other lower priority sequences.

11.2.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 254). There is a single averaging circuit and all input channels receive the same amount of averaging whether they are single-ended or differential.

11.2.4 Analog-to-Digital Converter

The converter itself generates a 10-bit output value for selected analog input. Special analog pads are used to minimize the distortion on the input.

11.2.5 Test Modes

There is a user-available test mode that allows for loopback operation within the digital portion of the ADC module. This can be useful for debugging software without having to provide actual analog stimulus. This mode is available through the **ADC Test Mode Loopback (ADCTMLB)** register (see page 267).

11.2.6 Internal Temperature Sensor

The internal temperature sensor provides an analog temperature reading as well as a reference voltage. The voltage at the output terminal SENSO is given by the following equation:

```
SENSO = 2.7 - ((T + 55) / 75)
```

This relation is shown in Figure 11-2 on page 240.

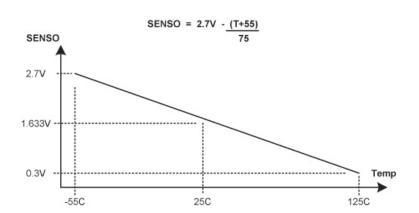

Figure 11-2. Internal Temperature Sensor Characteristic

11.3 Initialization and Configuration

In order for the ADC module to be used, the PLL must be enabled and using a supported crystal frequency (see the **RCC** register). Using unsupported frequencies can cause faulty operation in the ADC module.

11.3.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps. The main steps include enabling the clock to the ADC and reconfiguring the Sample Sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

- 1. Enable the ADC clock by writing a value of 0x0001.0000 to the RCGC1 register (see page 96).
- If required by the application, reconfigure the Sample Sequencer priorities in the ADCSSPRI
 register. The default configuration has Sample Sequencer 0 with the highest priority, and Sample
 Sequencer 3 as the lowest priority.

11.3.2 Sample Sequencer Configuration

Configuration of the Sample Sequencers is slightly more complex than the module initialization since each sample sequence is completely programmable.

The configuration for each Sample Sequencer should be as follows:

- Ensure that the Sample Sequencer is disabled by writing a 0 to the corresponding ASEN bit in the ADCACTSS register. Programming of the Sample Sequencers is allowed without having them enabled. Disabling the Sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
- 2. Configure the trigger event for the Sample Sequencer in the ADCEMUX register.
- For each sample in the sample sequence, configure the corresponding input source in the ADCSSMUXn register.

- 4. For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the ADCSSCTLn register. When programming the last nibble, ensure that the END bit is set. Failure to set the END bit causes unpredictable behavior.
- 5. If interrupts are to be used, write a 1 to the corresponding MASK bit in the ADCIM register.
- 6. Enable the Sample Sequencer logic by writing a 1 to the corresponding ASEN bit in the ADCACTSS register.

11.4 Register Map

Table 11-2 on page 241 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to the ADC base address of 0x4003.8000.

Table 11-2. ADC Register Map

11.5 Register Descriptions

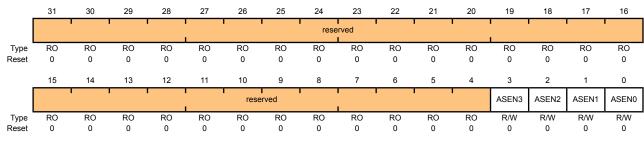

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000

This register controls the activation of the Sample Sequencers. Each Sample Sequencer can be enabled/disabled independently.

ADC Active Sample Sequencer (ADCACTSS)

Base 0x4003.8000 Offset 0x000 Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	ASEN3	R/W	0	ADC SS3 Enable
				Specifies whether Sample Sequencer 3 is enabled. If set, the sample sequence logic for Sequencer 3 is active. Otherwise, the Sequencer is inactive.
2	ASEN2	R/W	0	ADC SS2 Enable
				Specifies whether Sample Sequencer 2 is enabled. If set, the sample sequence logic for Sequencer 2 is active. Otherwise, the Sequencer is inactive.
1	ASEN1	R/W	0	ADC SS1 Enable
				Specifies whether Sample Sequencer 1 is enabled. If set, the sample sequence logic for Sequencer 1 is active. Otherwise, the Sequencer is inactive.
0	ASEN0	R/W	0	ADC SS0 Enable

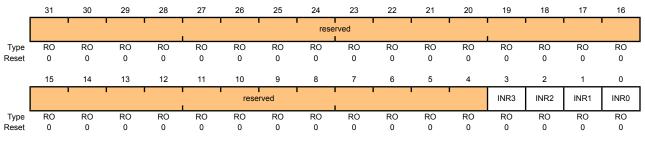

Specifies whether Sample Sequencer 0 is enabled. If set, the sample sequence logic for Sequencer 0 is active. Otherwise, the Sequencer is inactive.

Register 2: ADC Raw Interrupt Status (ADCRIS), offset 0x004

This register shows the status of the raw interrupt signal of each Sample Sequencer. These bits may be polled by software to look for interrupt conditions without having to generate controller interrupts.

ADC Raw Interrupt Status (ADCRIS)

Base 0x4003.8000 Offset 0x004 Type RO, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	INR3	RO	0	SS3 Raw Interrupt Status Set by hardware when a sample with its respective ADCSSCTL3 IE bit has completed conversion. This bit is cleared by writing a 1 to the ADCISC IN3 bit.
2	INR2	RO	0	SS2 Raw Interrupt Status Set by hardware when a sample with its respective ADCSSCTL2 IE bit has completed conversion. This bit is cleared by writing a 1 to the ADCISC IN2 bit.
1	INR1	RO	0	SS1 Raw Interrupt Status Set by hardware when a sample with its respective ADCSSCTL1 IE bit has completed conversion. This bit is cleared by writing a 1 to the ADCISC IN1 bit.
0	INR0	RO	0	SS0 Raw Interrupt Status

Set by hardware when a sample with its respective **ADCSSCTL0** IE bit has completed conversion. This bit is cleared by writing a 1 to the **ADCISC** IN0 bit.

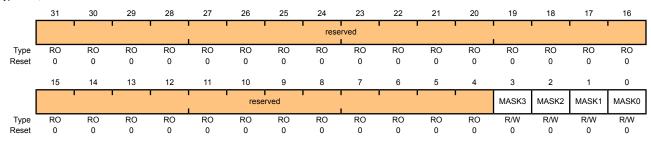

Register 3: ADC Interrupt Mask (ADCIM), offset 0x008

This register controls whether the Sample Sequencer raw interrupt signals are promoted to controller interrupts. The raw interrupt signal for each Sample Sequencer can be masked independently.

ADC Interrupt Mask (ADCIM)

Base 0x4003.8000

Offset 0x008
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	MASK3	R/W	0	SS3 Interrupt Mask
				Specifies whether the raw interrupt signal from Sample Sequencer 3 (ADCRIS register INR3 bit) is promoted to a controller interrupt. If set, the raw interrupt signal is promoted to a controller interrupt. Otherwise, it is not.
2	MASK2	R/W	0	SS2 Interrupt Mask
				Specifies whether the raw interrupt signal from Sample Sequencer 2 (ADCRIS register INR2 bit) is promoted to a controller interrupt. If set, the raw interrupt signal is promoted to a controller interrupt. Otherwise, it is not.
1	MASK1	R/W	0	SS1 Interrupt Mask
				Specifies whether the raw interrupt signal from Sample Sequencer 1 (ADCRIS register INR1 bit) is promoted to a controller interrupt. If set, the raw interrupt signal is promoted to a controller interrupt. Otherwise, it is not.
0	MASK0	R/W	0	SS0 Interrupt Mask

Specifies whether the raw interrupt signal from Sample Sequencer 0 (ADCRIS register ${\tt INR0}$ bit) is promoted to a controller interrupt. If set, the raw interrupt signal is promoted to a controller interrupt. Otherwise, it is not.

Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing interrupt conditions, and shows the status of controller interrupts generated by the Sample Sequencers. When read, each bit field is the logical AND of the respective INR and MASK bits. Interrupts are cleared by writing a 1 to the corresponding bit position. If software is polling the ADCRIS instead of generating interrupts, the INR bits are still cleared via the ADCISC register, even if the IN bit is not set.

ADC Interrupt Status and Clear (ADCISC)

Base 0x4003.8000 Offset 0x00C Type R/W1C, reset 0x0000.0000

a 1, and also clears the INRO bit.

Register 5: ADC Overflow Status (ADCOSTAT), offset 0x010

This register indicates overflow conditions in the Sample Sequencer FIFOs. Once the overflow condition has been handled by software, the condition can be cleared by writing a 1 to the corresponding bit position.

ADC Overflow Status (ADCOSTAT)

Name

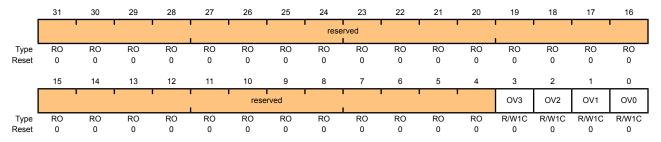

Type

Reset

Base 0x4003.8000

Bit/Field

Offset 0x010 Type R/W1C, reset 0x0000.0000

Description

31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	OV3	R/W1C	0	SS3 FIFO Overflow
				This bit specifies that the FIFO for Sample Sequencer 3 has hit an overflow condition where the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped and this bit is set by hardware to indicate the occurrence of dropped data. This bit is cleared by writing a 1.
2	OV2	R/W1C	0	SS2 FIFO Overflow
				This bit specifies that the FIFO for Sample Sequencer 2 has hit an overflow condition where the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped and this bit is set by hardware to indicate the occurrence of dropped data. This bit is cleared by writing a 1.
1	OV1	R/W1C	0	SS1 FIFO Overflow
				This bit specifies that the FIFO for Sample Sequencer 1 has hit an overflow condition where the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped and this bit is set by hardware to indicate the occurrence of dropped data. This bit is cleared by writing a 1.
0	OV0	R/W1C	0	SS0 FIFO Overflow

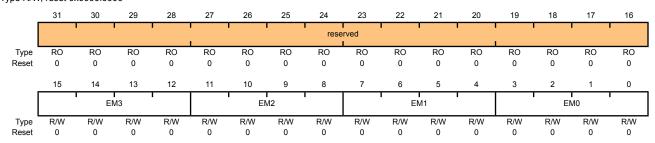

This bit specifies that the FIFO for Sample Sequencer 0 has hit an overflow condition where the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped and this bit is set by hardware to indicate the occurrence of dropped data. This bit is cleared by writing a 1.

Register 6: ADC Event Multiplexer Select (ADCEMUX), offset 0x014

The ADCEMUX selects the event (trigger) that initiates sampling for each Sample Sequencer. Each Sample Sequencer can be configured with a unique trigger source.

ADC Event Multiplexer Select (ADCEMUX)

Base 0x4003.8000 Offset 0x014 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description

				0x8 Reserved
				0x9-0xE reserved

Bit/Field	Name	Type	Reset	Descript	ion
3:0	EM0	R/W	0x00	SS0 Triç	gger Select
				This field	d selects the trigger source for Sample Sequencer 0.
				The vali	d configurations for this field are:
				Value	Event
				0x0	Controller (default)
				0x1	Analog Comparator 0
				0x2	Analog Comparator 1
				0x3	Reserved
				0x4	External (GPIO PB4)
				0x5	Timer
				0x6	PWM0
				0x7	PWM1
				8x0	Reserved
				0x9-0xE	E reserved
				0xF	Always (continuously sample)

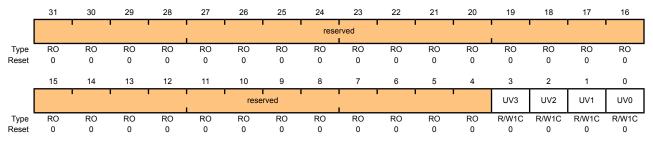

Register 7: ADC Underflow Status (ADCUSTAT), offset 0x018

This register indicates underflow conditions in the Sample Sequencer FIFOs. The corresponding underflow condition can be cleared by writing a 1 to the relevant bit position.

ADC Underflow Status (ADCUSTAT)

Base 0x4003.8000

Offset 0x018
Type R/W1C, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	UV3	R/W1C	0	SS3 FIFO Underflow
				This bit specifies that the FIFO for Sample Sequencer 3 has hit an underflow condition where the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned. This bit is cleared by writing a 1.
2	UV2	R/W1C	0	SS2 FIFO Underflow
				This bit specifies that the FIFO for Sample Sequencer 2 has hit an underflow condition where the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned. This bit is cleared by writing a 1.
1	UV1	R/W1C	0	SS1 FIFO Underflow
				This bit specifies that the FIFO for Sample Sequencer 1 has hit an underflow condition where the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned. This bit is cleared by writing a 1.
0	UV0	R/W1C	0	SS0 FIFO Underflow

This bit specifies that the FIFO for Sample Sequencer 0 has hit an underflow condition where the FIFO is empty and a read was requested. The problematic read does not move the FIFO pointers, and 0s are returned. This bit is cleared by writing a 1.

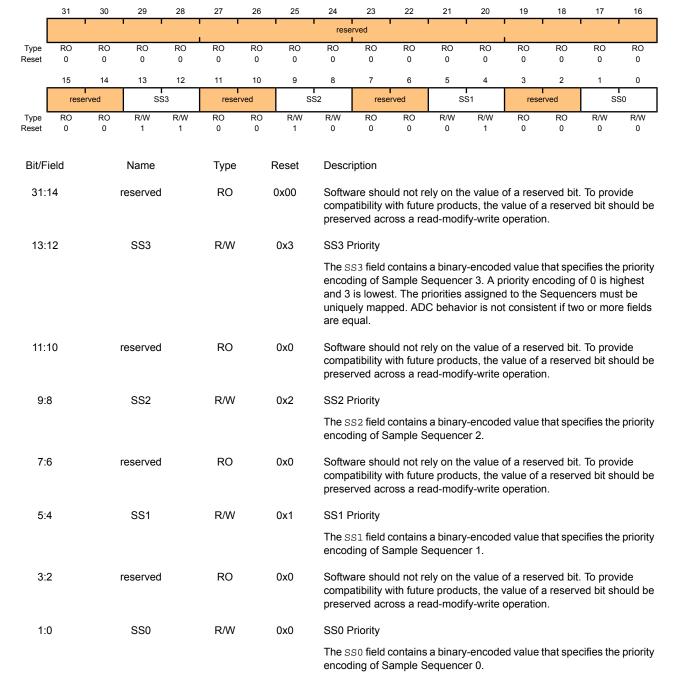

Register 8: ADC Sample Sequencer Priority (ADCSSPRI), offset 0x020

This register sets the priority for each of the Sample Sequencers. Out of reset, Sequencer 0 has the highest priority, and sample sequence 3 has the lowest priority. When reconfiguring sequence priorities, each sequence must have a unique priority or the ADC behavior is inconsistent.

ADC Sample Sequencer Priority (ADCSSPRI)

Base 0x4003.8000 Offset 0x020

Type R/W, reset 0x0000.3210

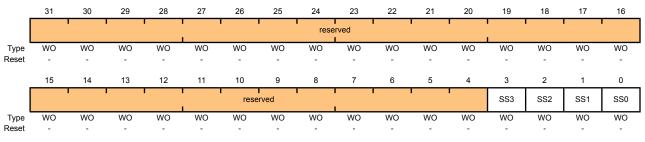

Register 9: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028

This register provides a mechanism for application software to initiate sampling in the Sample Sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

ADC Processor Sample Sequence Initiate (ADCPSSI)

Base 0x4003.8000 Offset 0x028 Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:4	reserved	WO	-	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	SS3	WO	-	SS3 Initiate
				Only a write by software is valid; a read of the register returns no meaningful data. When set by software, sampling is triggered on Sample Sequencer 3, assuming the Sequencer is enabled in the ADCACTSS register.
2	SS2	WO	-	SS2 Initiate
				Only a write by software is valid; a read of the register returns no meaningful data. When set by software, sampling is triggered on Sample Sequencer 2, assuming the Sequencer is enabled in the ADCACTSS register.
1	SS1	WO	-	SS1 Initiate
				Only a write by software is valid; a read of the register returns no meaningful data. When set by software, sampling is triggered on Sample Sequencer 1, assuming the Sequencer is enabled in the ADCACTSS register.
0	SS0	WO	-	SS0 Initiate
				Only a write by software is valid: a read of the register returns no

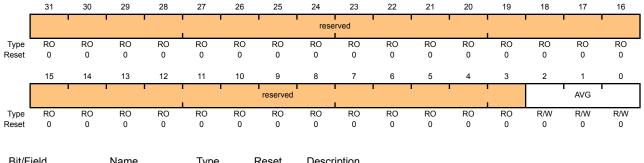

Only a write by software is valid; a read of the register returns no meaningful data. When set by software, sampling is triggered on Sample Sequencer 0, assuming the Sequencer is enabled in the **ADCACTSS** register.

Register 10: ADC Sample Averaging Control (ADCSAC), offset 0x030

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from 2^{AVG} consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG = 7 provides unpredictable results.

ADC Sample Averaging Control (ADCSAC)

Base 0x4003.8000 Offset 0x030 Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	AVG	R/W	0x0	Hardware Averaging Control

Specifies the amount of hardware averaging that will be applied to ADC samples. The AVG field can be any value between 0 and 6. Entering a value of 7 creates unpredictable results.

Value	Description
0x0	No hardware oversampling
0x1	2x hardware oversampling
0x2	4x hardware oversampling
0x3	8x hardware oversampling
0x4	16x hardware oversampling
0x5	32x hardware oversampling
0x6	64x hardware oversampling
0x7	Reserved

Register 11: ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0), offset 0x040

This register defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0.

Register 13: ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0), offset 0x048 Register 14: ADC Sample Sequence Result FIFO 1 (ADCSSFIFO1), offset 0x068 Register 15: ADC Sample Sequence Result FIFO 2 (ADCSSFIFO2), offset 0x088 Register 16: ADC Sample Sequence Result FIFO 3 (ADCSSFIFO3), offset 0x0A8

This register contains the conversion results for samples collected with the Sample Sequencer (the ADCSSFIFO0 register is used for Sample Sequencer 0, ADCSSFIFO1 for Sequencer 1, ADCSSFIFO2 for Sequencer 2, and ADCSSFIFO3 for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the ADCOSTAT and ADCUSTAT registers.

ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0)

Base 0x4003.8000 Offset 0x048 Type RO, reset 0x0000.0000

Register 17: ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0), offset 0x04C

Register 18: ADC Sample Sequence FIFO 1 Status (ADCSSFSTAT1), offset 0x06C

Register 19: ADC Sample Sequence FIFO 2 Status (ADCSSFSTAT2), offset 0x08C

Register 20: ADC Sample Sequence FIFO 3 Status (ADCSSFSTAT3), offset 0x0AC

This register provides a window into the Sample Sequencer, providing full/empty status information as well as the positions of the head and tail pointers. The reset value of 0x100 indicates an empty FIFO. The **ADCSSFSTAT0** register provides status on FIFO, **ADCSSFSTAT1** on FIFO1, **ADCSSFSTAT2** on FIFO2, and **ADCSSFSTAT3** on FIFO3.

Register 27: ADC Test Mode Loopback (ADCTMLB), offset 0x100

This register provides loopback operation within the digital logic of the ADC, which can be useful in debugging software without having to provide actual analog stimulus. This test mode is entered by writing a value of 0x0000.0001 to this register. When data is read from the FIFO in loopback mode, the read-only portion of this register is returned.

When set, forces a loopback within the digital block to provide information on input and unique numbering.

The 10-bit loopback data is defined as shown in the read for bits 9:0 above.

12 Universal Asynchronous Receivers/Transmitters (UARTs)

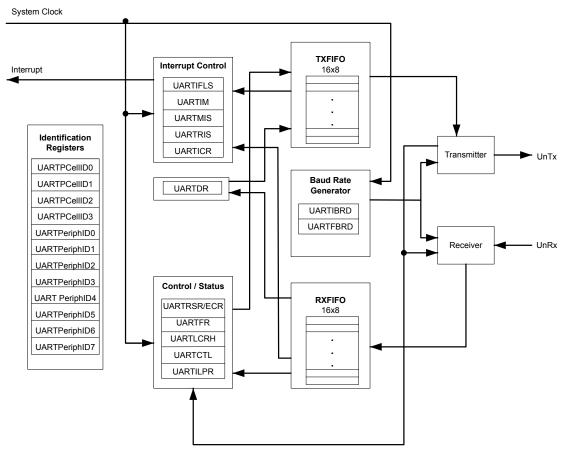

The Stellaris[®] Universal Asynchronous Receiver/Transmitter (UART) provides fully programmable, 16C550-type serial interface characteristics. The LM3S2432 controller is equipped with two UART modules.

Each UART has the following features:

- Separate transmit and receive FIFOs
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Programmable baud-rate generator allowing rates up to 3.125 Mbps
- Standard asynchronous communication bits for start, stop, and parity
- False start bit detection
- Line-break generation and detection
- Fully programmable serial interface characteristics:
 - 5, 6, 7, or 8 data bits
 - Even, odd, stick, or no-parity bit generation/detection
 - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing:
 - Programmable use of IrDA Serial InfraRed (SIR) or UART input/output
 - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
 - Support of normal 3/16 and low-power (1.41-2.23 µs) bit durations
 - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration

12.1 Block Diagram

Figure 12-1. UART Module Block Diagram

12.2 Functional Description

Each Stellaris[®] UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the TXE and RXE bits of the **UART Control** (**UARTCTL**) register (see page 288). Transmit and receive are both enabled out of reset. Before any control registers are programmed, the UART must be disabled by clearing the UARTEN bit in **UARTCTL**. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART peripheral also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the UARTCTL register.

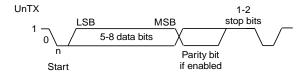

12.2.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit, and followed by the data

bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 12-2 on page 271 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

Figure 12-2. UART Character Frame

12.2.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divider allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 284) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 285). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the *BRD* and *BRDF* is the fractional part, separated by a decimal place.):

```
BRD = BRDI + BRDF = SysClk / (16 * Baud Rate)
```

The 6-bit fractional number (that is to be loaded into the DIVFRAC bit field in the **UARTFBRD** register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

```
UARTFBRD[DIVFRAC] = integer(BRDF * 64 + 0.5)
```

The UART generates an internal baud-rate reference clock at 16x the baud-rate (referred to as Baud16). This reference clock is divided by 16 to generate the transmit clock, and is used for error detection during receive operations.

Along with the **UART Line Control**, **High Byte (UARTLCRH)** register (see page 286), the **UARTIBRD** and **UARTFBRD** registers form an internal 30-bit register. This internal register is only updated when a write operation to **UARTLCRH** is performed, so any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- UARTIBRD write, UARTFBRD write, and UARTLCRH write
- UARTFBRD write, UARTIBRD write, and UARTLCRH write
- UARTIBRD write and UARTLCRH write
- UARTFBRD write and UARTLCRH write

12.2.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the **UARTLCRH** register. Data continues to be transmitted until there is no data left in the transmit FIFO. The BUSY bit in the **UART Flag (UARTFR)** register (see page 281) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The BUSY bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the UnRx is continuously 1) and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of Baud16 (described in "Transmit/Receive Logic" on page 270).

The start bit is valid if UnRx is still low on the eighth cycle of Baud16, otherwise a false start bit is detected and it is ignored. Start bit errors can be viewed in the **UART Receive Status (UARTRSR)** register (see page 279). If the start bit was valid, successive data bits are sampled on every 16th cycle of Baud16 (that is, one bit period later) according to the programmed length of the data characters. The parity bit is then checked if parity mode was enabled. Data length and parity are defined in the **UARTLCRH** register.

Lastly, a valid stop bit is confirmed if UnRx is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO, with any error bits associated with that word.

12.2.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream, and half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output, and decoded input to the UART. The UART signal pins can be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as high pulse of 3/16th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW. This drives the UART input pin LOW.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated IrLPBaud16 signal (1.63 μs, assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the UARTCR register.

Figure 12-3 on page 273 shows the UART transmit and receive signals, with and without IrDA modulation.

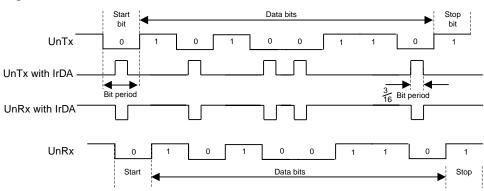

Figure 12-3. IrDA Data Modulation

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10 ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased, or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency, or receiver setup time.

12.2.5 FIFO Operation

The UART has two 16-entry FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the **UART Data (UARTDR)** register (see page 277). Read operations of the **UARTDR** register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the FEN bit in **UARTLCRH** (page 286).

FIFO status can be monitored via the **UART Flag (UARTFR)** register (see page 281) and the **UART Receive Status (UARTRSR)** register. Hardware monitors empty, full and overrun conditions. The **UARTFR** register contains empty and full flags (TXFE, TXFF, RXFE, and RXFF bits) and the **UARTRSR** register shows overrun status via the OE bit.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 290). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include 1/8, ½, ½, ¾, and 7/8. For example, if the ¼ option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the ½ mark.

12.2.6 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error

- Parity Error
- Framing Error
- Receive Timeout
- Transmit (when condition defined in the TXIFLSEL bit in the UARTIFLS register is met)
- Receive (when condition defined in the RXIFLSEL bit in the UARTIFLS register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 295).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM**) register (see page 292) by setting the corresponding IM bit to 1. If interrupts are not used, the raw interrupt status is always visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 294).

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by setting the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 296).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

12.2.7 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work. This is accomplished by setting the LBE bit in the **UARTCTL** register (see page 288). In loopback mode, data transmitted on UnTx is received on the UnRx input.

12.2.8 IrDA SIR block

The IrDA SIR block contains an IrDA serial IR (SIR) protocol encoder/decoder. When enabled, the SIR block uses the \mathtt{UnTx} and \mathtt{UnRx} pins for the SIR protocol, which should be connected to an IR transceiver.

The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception.

12.3 Initialization and Configuration

To use the UARTs, the peripheral clock must be enabled by setting the <code>UARTO</code> or <code>UART1</code> bits in the RCGC1 register.

This section discusses the steps that are required for using a UART module. For this example, the system clock is assumed to be 20 MHz and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit

- No parity
- FIFOs disabled
- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), since the **UARTIBRD** and **UARTFBRD** registers must be written before the **UARTLCRH** register. Using the equation described in "Baud-Rate Generation" on page 271, the BRD can be calculated:

```
BRD = 20,000,000 / (16 * 115,200) = 10.8507
```

which means that the DIVINT field of the **UARTIBRD** register (see page 284) should be set to 10. The value to be loaded into the **UARTFBRD** register (see page 285) is calculated by the equation:

```
UARTFBRD[DIVFRAC] = integer(0.8507 * 64 + 0.5) = 54
```

With the BRD values in hand, the UART configuration is written to the module in the following order:

- 1. Disable the UART by clearing the UARTEN bit in the **UARTCTL** register.
- Write the integer portion of the BRD to the **UARTIBRD** register.
- 3. Write the fractional portion of the BRD to the **UARTFBRD** register.
- **4.** Write the desired serial parameters to the **UARTLCRH** register (in this case, a value of 0x0000.0060).
- 5. Enable the UART by setting the UARTEN bit in the **UARTCTL** register.

12.4 Register Map

Table 12-1 on page 275 lists the UART registers. The offset listed is a hexadecimal increment to the register's address, relative to that UART's base address:

UART0: 0x4000.C000

UART1: 0x4000.D000

Note: The UART must be disabled (see the UARTEN bit in the **UARTCTL** register on page 288) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

Table 12-1. UART Register Map

12.5 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

Register 1: UART Data (UARTDR), offset 0x000

This register is the data register (the interface to the FIFOs).

When FIFOs are enabled, data written to this location is pushed onto the transmit FIFO. If FIFOs are disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

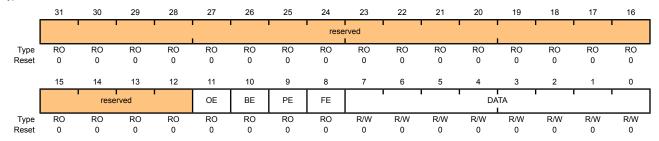

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If FIFOs are disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

UART Data (UARTDR)

UART0 base: 0x4000.C000 UART1 base: 0x4000.D000

Offset 0x000

Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	OE	RO	0	UART Overrun Error The OE values are defined as follows: Value Description 0 There has been no data loss due to a FIFO overrun. 1 New data was received when the FIFO was full, resulting in data loss.
10	BE	RO	0	UART Break Error

This bit is set to 1 when a break condition is detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).

In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the received data input goes to a 1 (marking state) and the next valid start bit is received.

Bit/Field	Name	Type	Reset	Description
9	PE	RO	0	UART Parity Error
				This bit is set to 1 when the parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.
				In FIFO mode, this error is associated with the character at the top of the FIFO.
8	FE	RO	0	UART Framing Error
				This bit is set to 1 when the received character does not have a valid stop bit (a valid stop bit is 1).
7:0	DATA	R/W	0	Data Transmitted or Received
				When written, the data that is to be transmitted via the UART. When read, the data that was received by the UART.

Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

Type

RO

Reset

0

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared to 0 on reset.

Read-Only Receive Status (UARTRSR) Register

Name

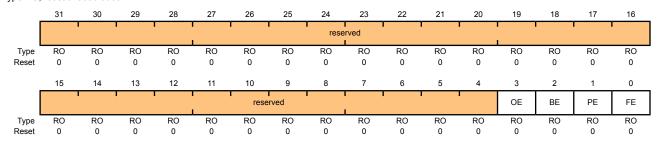

reserved

UART Receive Status/Error Clear (UARTRSR/UARTECR)

UART0 base: 0x4000.C000 UART1 base: 0x4000.D000 Offset 0x004 Type RO, reset 0x0000.0000

Bit/Field

31:4

Description

				compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	OE	RO	0	UART Overrun Error
				When this bit is set to 1, data is received and the FIFO is already full. This bit is cleared to 0 by a write to UARTECR .
				The FIFO contents remain valid since no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must now read the data in order to empty the FIFO.
2	BE	RO	0	UART Break Error

This bit is set to 1 when a break condition is detected, indicating that the received data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).

Software should not rely on the value of a reserved bit. To provide

This bit is cleared to 0 by a write to **UARTECR**.

In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received.

Bit/Field	Name	Type	Reset	Description
1	PE	RO	0	UART Parity Error
				This bit is set to 1 when the parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register.
				This bit is cleared to 0 by a write to UARTECR .
0	FE	RO	0	UART Framing Error
				This bit is set to 1 when the received character does not have a valid

stop bit (a valid stop bit is 1).

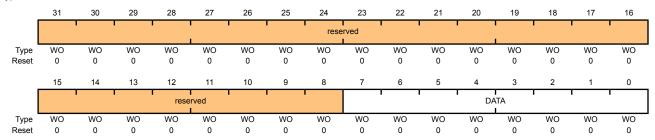

This bit is cleared to 0 by a write to **UARTECR**.

In FIFO mode, this error is associated with the character at the top of the FIFO.

Write-Only Error Clear (UARTECR) Register

UART Receive Status/Error Clear (UARTRSR/UARTECR)

UART0 base: 0x4000.C000 UART1 base: 0x4000.D000 Offset 0x004 Type WO, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:8	reserved	WO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DATA	WO	0	Error Clear

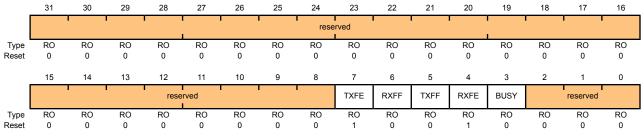

A write to this register of any data clears the framing, parity, break, and overrun flags.

Register 3: UART Flag (UARTFR), offset 0x018

The **UARTFR** register is the flag register. After reset, the TXFF, RXFF, and BUSY bits are 0, and TXFE and RXFE bits are 1.

UART Flag (UARTFR)

UART0 base: 0x4000.C000 UART1 base: 0x4000.D000 Offset 0x018 Type RO, reset 0x0000.0090

Bit/Field	Name	Туре	Reset	Description
31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	TXFE	RO	1	UART Transmit FIFO Empty
				The meaning of this bit depends on the state of the ${\tt FEN}$ bit in the ${\tt UARTLCRH}$ register.
				If the FIFO is disabled (FEN is 0), this bit is set when the transmit holding register is empty.
				If the FIFO is enabled (FEN is 1), this bit is set when the transmit FIFO is empty.
6	RXFF	RO	0	UART Receive FIFO Full
				The meaning of this bit depends on the state of the ${\tt FEN}$ bit in the ${\tt UARTLCRH}$ register.
				If the FIFO is disabled, this bit is set when the receive holding register is full.
				If the FIFO is enabled, this bit is set when the receive FIFO is full.
5	TXFF	RO	0	UART Transmit FIFO Full
				The meaning of this bit depends on the state of the ${\tt FEN}$ bit in the ${\tt UARTLCRH}$ register.

If the FIFO is disabled, this bit is set when the transmit holding register is full.

If the FIFO is enabled, this bit is set when the transmit FIFO is full.

Bit/Field	Name	Туре	Reset	Description
4	RXFE	RO	1	UART Receive FIFO Empty
				The meaning of this bit depends on the state of the ${\tt FEN}$ bit in the ${\tt UARTLCRH}$ register.
				If the FIFO is disabled, this bit is set when the receive holding register is empty.
				If the FIFO is enabled, this bit is set when the receive FIFO is empty.
3	BUSY	RO	0	UART Busy
				When this bit is 1, the UART is busy transmitting data. This bit remains set until the complete byte, including all stop bits, has been sent from the shift register.
				This bit is set as soon as the transmit FIFO becomes non-empty (regardless of whether UART is enabled).
2:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020

The **UARTILPR** register is an 8-bit read/write register that stores the low-power counter divisor value used to generate the <code>IrlPBaud16</code> signal by dividing down the system clock (SysClk). All the bits are cleared to 0 when reset.

The IrlpBaud16 internal signal is generated by dividing down the UARTCLK signal according to the low-power divisor value written to **UARTILPR**. The low-power divisor value is calculated as follows:

ILPDVSR = SysClk / F_{IrLPBaud16}

where $F_{IrLPBaud16}$ is nominally 1.8432 MHz.

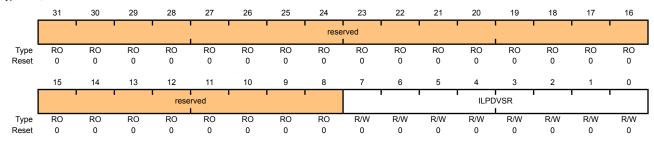

IrlpBaud16 is an internal signal used for SIR pulse generation when low-power mode is used. You must choose the divisor so that $1.42\,\mathrm{MHz} < \mathrm{F_{IrlpBaud16}} < 2.12\,\mathrm{MHz}$, which results in a low-power pulse duration of $1.41-2.11\,\mu\mathrm{s}$ (three times the period of IrlpBaud16). The minimum frequency of IrlpBaud16 ensures that pulses less than one period of IrlpBaud16 are rejected, but that pulses greater than $1.4\,\mu\mathrm{s}$ are accepted as valid pulses.

Note: Zero is an illegal value. Programming a zero value results in no IrlPBaud16 pulses being generated.

UART IrDA Low-Power Register (UARTILPR)

UART0 base: 0x4000.C000 UART1 base: 0x4000.D000 Offset 0x020

Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	ILPDVSR	R/W	0x00	IrDA Low-Power Divisor

This is an 8-bit low-power divisor value.

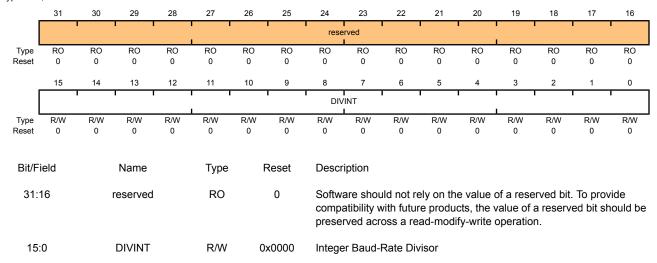

Register 5: UART Integer Baud-Rate Divisor (UARTIBRD), offset 0x024

The **UARTIBRD** register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when **UARTIBRD**=0), in which case the **UARTFBRD** register is ignored. When changing the **UARTIBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See "Baud-Rate Generation" on page 271 for configuration details.

UART Integer Baud-Rate Divisor (UARTIBRD)

UART0 base: 0x4000.C000 UART1 base: 0x4000.D000 Offset 0x024

Type R/W, reset 0x0000.0000

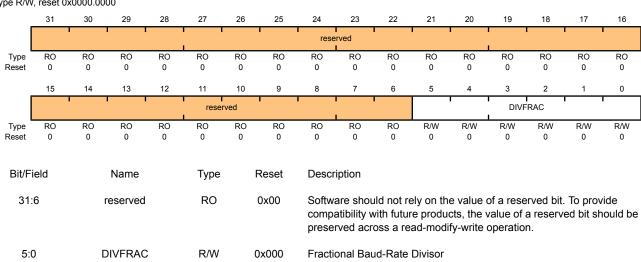

Register 6: UART Fractional Baud-Rate Divisor (UARTFBRD), offset 0x028

The **UARTFBRD** register is the fractional part of the baud-rate divisor value. All the bits are cleared on reset. When changing the UARTFBRD register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See "Baud-Rate Generation" on page 271 for configuration details.

UART Fractional Baud-Rate Divisor (UARTFBRD)

UART0 base: 0x4000.C000 UART1 base: 0x4000.D000 Offset 0x028

Type R/W, reset 0x0000.0000

Register 7: UART Line Control (UARTLCRH), offset 0x02C

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

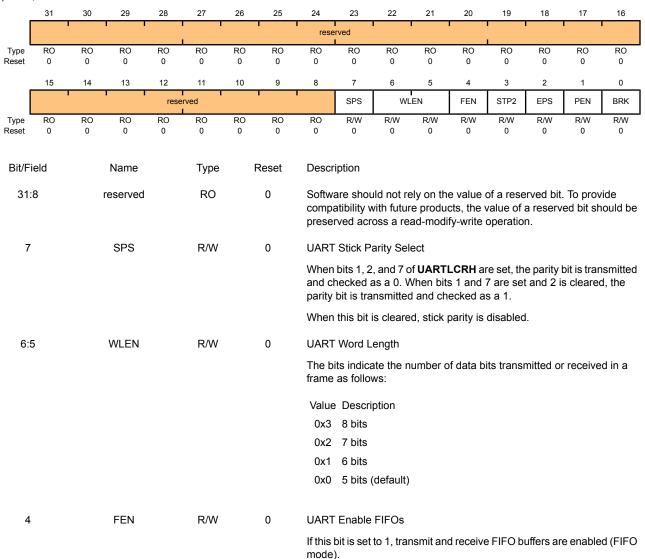

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

UART Line Control (UARTLCRH)

UART0 base: 0x4000.C000 UART1 base: 0x4000.D000

Offset 0x02C

Type R/W, reset 0x0000.0000

When cleared to 0, FIFOs are disabled (Character mode). The FIFOs

become 1-byte-deep holding registers.

Bit/Field	Name	Туре	Reset	Description
3	STP2	R/W	0	UART Two Stop Bits Select
				If this bit is set to 1, two stop bits are transmitted at the end of a frame. The receive logic does not check for two stop bits being received.
2	EPS	R/W	0	UART Even Parity Select
				If this bit is set to 1, even parity generation and checking is performed during transmission and reception, which checks for an even number of 1s in data and parity bits.
				When cleared to 0, then odd parity is performed, which checks for an odd number of 1s.
				This bit has no effect when parity is disabled by the ${\tt PEN}$ bit.
1	PEN	R/W	0	UART Parity Enable
				If this bit is set to 1, parity checking and generation is enabled; otherwise, parity is disabled and no parity bit is added to the data frame.
0	BRK	R/W	0	UART Send Break
				If this bit is set to 1, a Low level is continually output on the ${\tt UnTX}$ output, after completing transmission of the current character. For the proper execution of the break command, the software must set this bit for at least two frames (character periods). For normal use, this bit must be cleared to 0.

Register 8: UART Control (UARTCTL), offset 0x030

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set to 1.

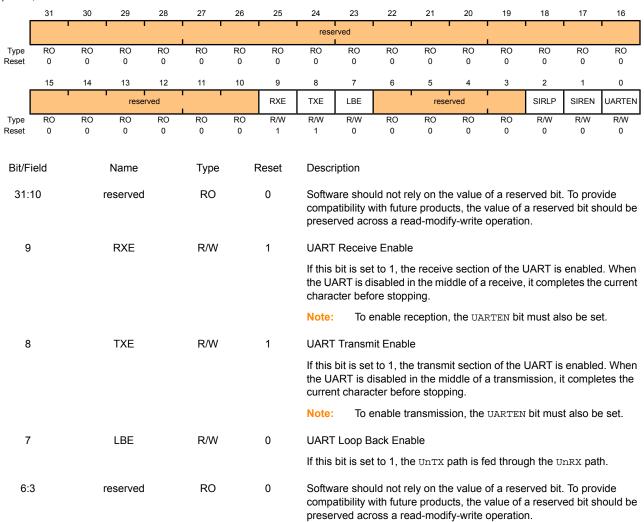

To enable the UART module, the UARTEN bit must be set to 1. If software requires a configuration change in the module, the UARTEN bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

UART Control (UARTCTL)

UART0 base: 0x4000.C000 UART1 base: 0x4000.D000

Offset 0x030

Type R/W, reset 0x0000.0300

Bit/Field	Name	Туре	Reset	Description
2	SIRLP	R/W	0	UART SIR Low Power Mode
				This bit selects the IrDA encoding mode. If this bit is cleared to 0, low-level bits are transmitted as an active High pulse with a width of 3/16th of the bit period. If this bit is set to 1, low-level bits are transmitted with a pulse width which is 3 times the period of the IrLPBaud16 input signal, regardless of the selected bit rate. Setting this bit uses less power, but might reduce transmission distances. See page 283 for more information.
1	SIREN	R/W	0	UART SIR Enable
				If this bit is set to 1, the IrDA SIR block is enabled, and the UART will transmit and receive data using SIR protocol.
0	UARTEN	R/W	0	UART Enable
				If this bit is set to 1, the UART is enabled. When the UART is disabled in the middle of transmission or reception, it completes the current character before stopping.

Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the TXRIS and RXRIS bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

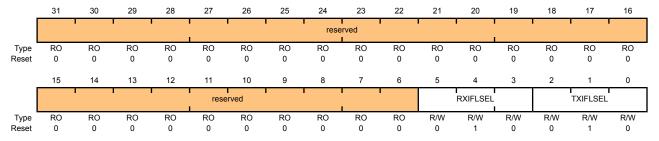

Out of reset, the TXIFLSEL and RXIFLSEL bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

UART Interrupt FIFO Level Select (UARTIFLS)

UART0 base: 0x4000.C000 UART1 base: 0x4000.D000

Offset 0x034

Type R/W, reset 0x0000.0012

Bit/Field	Name	Туре	Reset	Description

5:3	RXIFLSEL	R/W	0x2	UART Receive Interrupt FIFO Level Select

The trigger points for the receive interrupt are as follows:

Value Description

0x0 RX FIFO ≥ 1/8 full

0x1 RX FIFO ≥ $\frac{1}{4}$ full

0x2 RX FIFO ≥ $\frac{1}{2}$ full (default)

0x3 RX FIFO ≥ $\frac{3}{4}$ full

0x4 RX FIFO ≥ 7/8 full

0x5-0x7 Reserved

Bit/Field	Name	Type	Reset	Description
2:0	TXIFLSEL	R/W	0x2	UART Transmit Interrupt FIFO Level Select
				The trigger points for the transmit interrupt are as follows:
				Value Description
				0x0 TX FIFO ≤ 1/8 full
				0x1 TX FIFO ≤ ¼ full
				0x2 TX FIFO ≤ ½ full (default)
				0x3 TX FIFO ≤ ¾ full
				0x4 TX FIFO ≤ 7/8 full
				0x5-0x7 Reserved

Register 10: UART Interrupt Mask (UARTIM), offset 0x038

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Writing a 1 to a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Writing a 0 prevents the raw interrupt signal from being sent to the interrupt controller.

UART Interrupt Mask (UARTIM)

13 Synchronous Serial Interface (SSI)

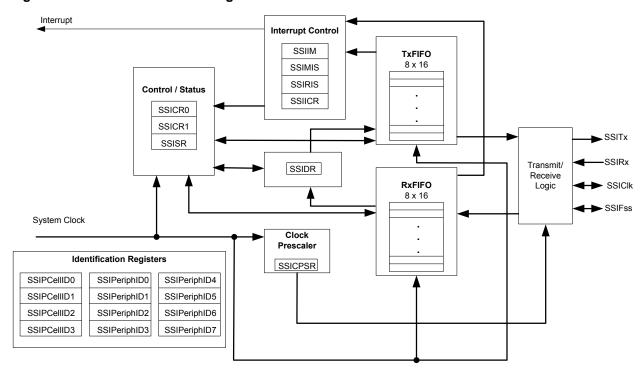

The Stellaris[®] Synchronous Serial Interface (SSI) is a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces.

The Stellaris® SSI module has the following features:

- Master or slave operation
- Programmable clock bit rate and prescale
- Separate transmit and receive FIFOs, 16 bits wide, 8 locations deep
- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing

13.1 Block Diagram

Figure 13-1. SSI Module Block Diagram

13.2 Functional Description

The SSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with

internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes.

13.2.1 Bit Rate Generation

The SSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the 50-MHz input clock. The clock is first divided by an even prescale value CPSDVSR from 2 to 254, which is programmed in the **SSI Clock Prescale** (**SSICPSR**) register (see page 329). The clock is further divided by a value from 1 to 256, which is 1 + SCR, where SCR is the value programmed in the **SSI Control0** (**SSICR0**) register (see page 322).

The frequency of the output clock SSIClk is defined by:

```
FSSIClk = FSysClk / (CPSDVSR * (1 + SCR))
```

Note that although the SSIC1k transmit clock can theoretically be 25 MHz, the module may not be able to operate at that speed. For master mode, the system clock must be at least two times faster than the SSIC1k. For slave mode, the system clock must be at least 12 times faster than the SSIC1k.

See "Synchronous Serial Interface (SSI)" on page 489 to view SSI timing parameters.

13.2.2 FIFO Operation

13.2.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 326), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to serial conversion and transmission to the attached slave or master, respectively, through the SSITX pin.

13.2.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data from the serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register.

When configured as a master or slave, serial data received through the SSIRx pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

13.2.3 Interrupts

The SSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service
- Receive FIFO service
- Receive FIFO time-out
- Receive FIFO overrun

All of the interrupt events are ORed together before being sent to the interrupt controller, so the SSI can only generate a single interrupt request to the controller at any given time. You can mask each

of the four individual maskable interrupts by setting the appropriate bits in the **SSI Interrupt Mask** (**SSIIM**) register (see page 330). Setting the appropriate mask bit to 1 enables the interrupt.

Provision of the individual outputs, as well as a combined interrupt output, allows use of either a global interrupt service routine, or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 332 and page 333, respectively).

13.2.4 Frame Formats

Each data frame is between 4 and 16 bits long, depending on the size of data programmed, and is transmitted starting with the MSB. There are three basic frame types that can be selected:

- Texas Instruments synchronous serial
- Freescale SPI
- MICROWIRE

For all three formats, the serial clock (SSIClk) is held inactive while the SSI is idle, and SSIClk transitions at the programmed frequency only during active transmission or reception of data. The idle state of SSIClk is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI and MICROWIRE frame formats, the serial frame (SSIFss) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

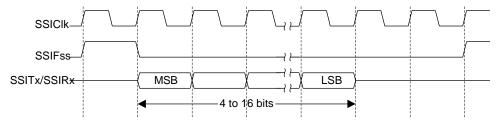

For Texas Instruments synchronous serial frame format, the SSIFss pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the SSI and the off-chip slave device drive their output data on the rising edge of SSIClk, and latch data from the other device on the falling edge.

Unlike the full-duplex transmission of the other two frame formats, the MICROWIRE format uses a special master-slave messaging technique, which operates at half-duplex. In this mode, when a frame begins, an 8-bit control message is transmitted to the off-chip slave. During this transmit, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the requested data. The returned data can be 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

13.2.4.1 Texas Instruments Synchronous Serial Frame Format

Figure 13-2 on page 312 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

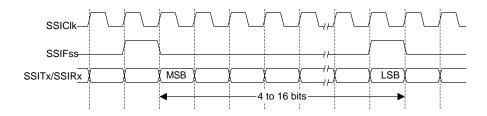

In this mode, SSIC1k and SSIFSS are forced Low, and the transmit data line SSITX is tristated whenever the SSI is idle. Once the bottom entry of the transmit FIFO contains data, SSIFSS is pulsed High for one SSIC1k period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of SSIC1k, the MSB of the 4 to 16-bit data frame is shifted out on the SSITX pin. Likewise, the MSB of the received data is shifted onto the SSIRX pin by the off-chip serial slave device.

Both the SSI and the off-chip serial slave device then clock each data bit into their serial shifter on the falling edge of each SSIClk. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of SSIClk after the LSB has been latched.

Figure 13-3 on page 313 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

Figure 13-3. TI Synchronous Serial Frame Format (Continuous Transfer)

13.2.4.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the SSIFss signal behaves as a slave select. The main feature of the Freescale SPI format is that the inactive state and phase of the SSIC1k signal are programmable through the SPO and SPH bits within the **SSISCR0** control register.

SPO Clock Polarity Bit

When the SPO clock polarity control bit is Low, it produces a steady state Low value on the SSIClk pin. If the SPO bit is High, a steady state High value is placed on the SSIClk pin when data is not being transferred.

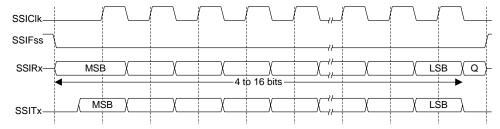

SPH Phase Control Bit

The SPH phase control bit selects the clock edge that captures data and allows it to change state. It has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the SPH phase control bit is Low, data is captured on the first clock edge transition. If the SPH bit is High, data is captured on the second clock edge transition.

13.2.4.3 Freescale SPI Frame Format with SPO=0 and SPH=0

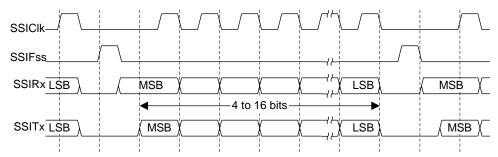

Single and continuous transmission signal sequences for Freescale SPI format with SPO=0 and SPH=0 are shown in Figure 13-4 on page 314 and Figure 13-5 on page 314.

Figure 13-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0

Note: Q is undefined.

Figure 13-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0

In this configuration, during idle periods:

- SSIC1k is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low. This causes slave data to be enabled onto the SSIRx input line of the master. The master SSITx output pad is enabled.

One half \mathtt{SSIClk} period later, valid master data is transferred to the \mathtt{SSITx} pin. Now that both the master and slave data have been set, the \mathtt{SSIClk} master clock pin goes High after one further half \mathtt{SSIClk} period.

The data is now captured on the rising and propagated on the falling edges of the SSIC1k signal.

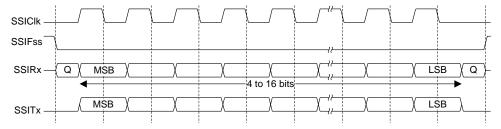

In the case of a single word transmission, after all bits of the data word have been transferred, the SSIFss line is returned to its idle High state one SSIC1k period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSIFss signal must be pulsed High between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is logic zero. Therefore, the master device must raise the SSIFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSIFss pin is returned to its idle state one SSIClk period after the last bit has been captured.

13.2.4.4 Freescale SPI Frame Format with SPO=0 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=0 and SPH=1 is shown in Figure 13-6 on page 315, which covers both single and continuous transfers.

Figure 13-6. Freescale SPI Frame Format with SPO=0 and SPH=1

Note: Q is undefined.

In this configuration, during idle periods:

- SSIC1k is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low. The master SSITx output is enabled. After a further one half SSIClk period, both master and slave valid data is enabled onto their respective transmission lines. At the same time, the SSIClk is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the SSIC1k signal.

In the case of a single word transfer, after all bits have been transferred, the SSIFss line is returned to its idle High state one SSIClk period after the last bit has been captured.

For continuous back-to-back transfers, the SSIFss pin is held Low between successive data words and termination is the same as that of the single word transfer.

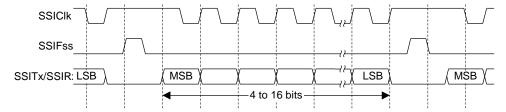

13.2.4.5 Freescale SPI Frame Format with SPO=1 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=1 and SPH=0 are shown in Figure 13-7 on page 316 and Figure 13-8 on page 316.

Figure 13-7. Freescale SPI Frame Format (Single Transfer) with SPO=1 and SPH=0

Note: Q is undefined.

Figure 13-8. Freescale SPI Frame Format (Continuous Transfer) with SPO=1 and SPH=0

In this configuration, during idle periods:

- SSIC1k is forced High
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low, which causes slave data to be immediately transferred onto the SSIRx line of the master. The master SSITx output pad is enabled.

One half period later, valid master data is transferred to the \mathtt{SSITx} line. Now that both the master and slave data have been set, the \mathtt{SSIClk} master clock pin becomes Low after one further half \mathtt{SSIClk} period. This means that data is captured on the falling edges and propagated on the rising edges of the \mathtt{SSIClk} signal.

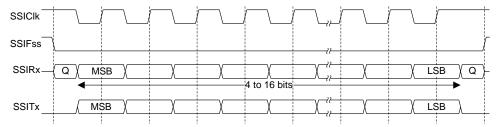

In the case of a single word transmission, after all bits of the data word are transferred, the SSIFss line is returned to its idle High state one SSIClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSIFss signal must be pulsed High between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is logic zero. Therefore, the master device must raise the SSIFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSIFss pin is returned to its idle state one SSIClk period after the last bit has been captured.

13.2.4.6 Freescale SPI Frame Format with SPO=1 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=1 and SPH=1 is shown in Figure 13-9 on page 317, which covers both single and continuous transfers.

Figure 13-9. Freescale SPI Frame Format with SPO=1 and SPH=1

Note: Q is undefined.

In this configuration, during idle periods:

- SSIC1k is forced High
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low. The master SSITx output pad is enabled. After a further one-half SSIClk period, both master and slave data are enabled onto their respective transmission lines. At the same time, SSIClk is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SSIClk signal.

After all bits have been transferred, in the case of a single word transmission, the SSIFss line is returned to its idle high state one SSIClk period after the last bit has been captured.

For continuous back-to-back transmissions, the SSIFss pin remains in its active Low state, until the final bit of the last word has been captured, and then returns to its idle state as described above.

For continuous back-to-back transfers, the SSIFss pin is held Low between successive data words and termination is the same as that of the single word transfer.

13.2.4.7 MICROWIRE Frame Format

Figure 13-10 on page 318 shows the MICROWIRE frame format, again for a single frame. Figure 13-11 on page 319 shows the same format when back-to-back frames are transmitted.

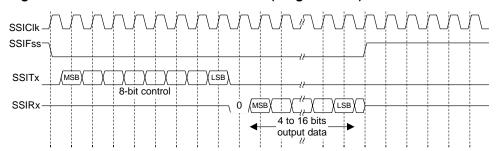

Figure 13-10. MICROWIRE Frame Format (Single Frame)

MICROWIRE format is very similar to SPI format, except that transmission is half-duplex instead of full-duplex, using a master-slave message passing technique. Each serial transmission begins with an 8-bit control word that is transmitted from the SSI to the off-chip slave device. During this transmission, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the required data. The returned data is 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

In this configuration, during idle periods:

- SSIC1k is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low

A transmission is triggered by writing a control byte to the transmit FIFO. The falling edge of SSIFss causes the value contained in the bottom entry of the transmit FIFO to be transferred to the serial shift register of the transmit logic, and the MSB of the 8-bit control frame to be shifted out onto the SSITxpin. SSIFss remains Low for the duration of the frame transmission. The SSIRxpin pin remains tristated during this transmission.

The off-chip serial slave device latches each control bit into its serial shifter on the rising edge of each SSIClk. After the last bit is latched by the slave device, the control byte is decoded during a one clock wait-state, and the slave responds by transmitting data back to the SSI. Each bit is driven onto the SSIRx line on the falling edge of SSIClk. The SSI in turn latches each bit on the rising edge of SSIClk. At the end of the frame, for single transfers, the SSIFss signal is pulled High one clock period after the last bit has been latched in the receive serial shifter, which causes the data to be transferred to the receive FIFO.

Note: The off-chip slave device can tristate the receive line either on the falling edge of SSIC1k after the LSB has been latched by the receive shifter, or when the SSIFss pin goes High.

For continuous transfers, data transmission begins and ends in the same manner as a single transfer. However, the SSIFSS line is continuously asserted (held Low) and transmission of data occurs back-to-back. The control byte of the next frame follows directly after the LSB of the received data from the current frame. Each of the received values is transferred from the receive shifter on the falling edge of SSIClk, after the LSB of the frame has been latched into the SSI.

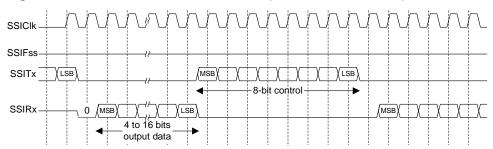

Figure 13-11. MICROWIRE Frame Format (Continuous Transfer)

In the MICROWIRE mode, the SSI slave samples the first bit of receive data on the rising edge of SSIClk after SSIFss has gone Low. Masters that drive a free-running SSIClk must ensure that the SSIFss signal has sufficient setup and hold margins with respect to the rising edge of SSIClk.

Figure 13-12 on page 319 illustrates these setup and hold time requirements. With respect to the SSIClk rising edge on which the first bit of receive data is to be sampled by the SSI slave, SSIFss must have a setup of at least two times the period of SSIClk on which the SSI operates. With respect to the SSIClk rising edge previous to this edge, SSIFss must have a hold of at least one SSIClk period.

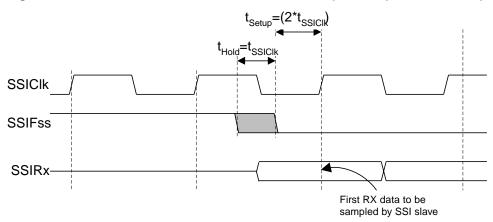

Figure 13-12. MICROWIRE Frame Format, SSIFss Input Setup and Hold Requirements

13.3 Initialization and Configuration

To use the SSI, its peripheral clock must be enabled by setting the SSI bit in the **RCGC1** register. For each of the frame formats, the SSI is configured using the following steps:

- 1. Ensure that the SSE bit in the **SSICR1** register is disabled before making any configuration changes.
- 2. Select whether the SSI is a master or slave:
 - **a.** For master operations, set the **SSICR1** register to 0x0000.0000.
 - **b.** For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
 - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
- 3. Configure the clock prescale divisor by writing the **SSICPSR** register.

- 4. Write the **SSICR0** register with the following configuration:
 - Serial clock rate (SCR)
 - Desired clock phase/polarity, if using Freescale SPI mode (SPH and SPO)
 - The protocol mode: Freescale SPI, TI SSF, MICROWIRE (FRF)
 - The data size (DSS)
- 5. Enable the SSI by setting the SSE bit in the SSICR1 register.

As an example, assume the SSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (SPO=1, SPH=1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

```
FSSIClk = FSysClk / (CPSDVSR * (1 + SCR))
1x106 = 20x106 / (CPSDVSR * (1 + SCR))
```

In this case, if CPSDVSR=2, SCR must be 9.

The configuration sequence would be as follows:

- 1. Ensure that the SSE bit in the SSICR1 register is disabled.
- Write the SSICR1 register with a value of 0x0000.0000.
- 3. Write the **SSICPSR** register with a value of 0x0000.0002.
- 4. Write the **SSICR0** register with a value of 0x0000.09C7.
- 5. The SSI is then enabled by setting the SSE bit in the **SSICR1** register to 1.

13.4 Register Map

Table 13-1 on page 320 lists the SSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that SSI module's base address:

SSI0: 0x4000.8000

Note: The SSI must be disabled (see the SSE bit in the **SSICR1** register) before any of the control registers are reprogrammed.

Table 13-1. SSI Register Map

13.5 Register Descriptions

The remainder of this section lists and describes the SSI registers, in numerical order by address offset.

Register 1: SSI Control 0 (SSICR0), offset 0x000

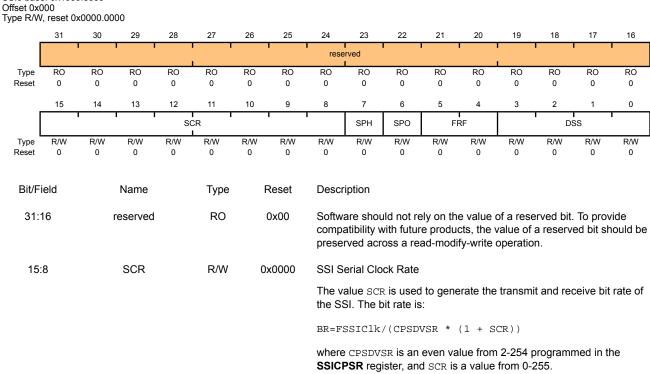

SSICR0 is control register 0 and contains bit fields that control various functions within the SSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

SSI Control 0 (SSICR0)

SSI0 base: 0x4000.8000

7

SPH

SSI Serial Clock Phase

This bit is only applicable to the Freescale SPI Format.

The SPH control bit selects the clock edge that captures data and allows it to change state. It has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge.

When the SPH bit is 0, data is captured on the first clock edge transition. If SPH is 1, data is captured on the second clock edge transition.

R/W 6 SPO 0 SSI Serial Clock Polarity

R/W

0

This bit is only applicable to the Freescale SPI Format.

When the SPO bit is 0, it produces a steady state Low value on the SSIC1k pin. If SPO is 1, a steady state High value is placed on the SSIC1k pin when data is not being transferred.

Bit/Field	Name	Туре	Reset	Description
5:4	FRF	R/W	0x0	SSI Frame Format Select
				The FRF values are defined as follows:
				Value Frame Format
				0x0 Freescale SPI Frame Format
				0x1 Texas Intruments Synchronous Serial Frame Format
				0x2 MICROWIRE Frame Format
				0x3 Reserved
3:0	DSS	R/W	0x00	SSI Data Size Select
				The DSS values are defined as follows:
				Value Data Size
				0x0-0x2 Reserved
				0x3 4-bit data
				0x4 5-bit data
				0x5 6-bit data
				0x6 7-bit data
				0x7 8-bit data
				0x8 9-bit data
				0x9 10-bit data
				0xA 11-bit data
				0xB 12-bit data
				0xC 13-bit data
				0xD 14-bit data
				0xE 15-bit data
				0xF 16-bit data

Register 2: SSI Control 1 (SSICR1), offset 0x004

SSICR1 is control register 1 and contains bit fields that control various functions within the SSI module. Master and slave mode functionality is controlled by this register.

SSI Control 1 (SSICR1)

SSI0 base: 0x4000.8000

		71.		· · · · · ·
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Description

SSI Slave Mode Output Disable

This bit is relevant only in the Slave mode (MS=1). In multiple-slave systems, it is possible for the SSI master to broadcast a message to all slaves in the system while ensuring that only one slave drives data onto the serial output line. In such systems, the TXD lines from multiple slaves could be tied together. To operate in such a system, the SOD bit can be configured so that the SSI slave does not drive the SSITx pin.

The SOD values are defined as follows:

Value Description

- SSI can drive SSITx output in Slave Output mode.
- SSI must not drive the ${\tt SSITx}$ output in Slave mode.

2 MS R/W 0 SSI Master/Slave Select

Type

R/W

Reset

0

This bit selects Master or Slave mode and can be modified only when SSI is disabled (SSE=0).

The MS values are defined as follows:

Value Description

- Device configured as a master.
- Device configured as a slave.

Bit/Field	Name	Туре	Reset	Description
1	SSE	R/W	0	SSI Synchronous Serial Port Enable Setting this bit enables SSI operation. The SSE values are defined as follows: Value Description 0 SSI operation disabled.
				1 SSI operation enabled.
				Note: This bit must be set to 0 before any control registers are reprogrammed.
0	LBM	R/W	0	SSI Loopback Mode
				Setting this bit enables Loopback Test mode.
				The LBM values are defined as follows:

Value Description

- 0 Normal serial port operation enabled.
- Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.

Register 3: SSI Data (SSIDR), offset 0x008

SSIDR is the data register and is 16-bits wide. When **SSIDR** is read, the entry in the receive FIFO (pointed to by the current FIFO read pointer) is accessed. As data values are removed by the SSI receive logic from the incoming data frame, they are placed into the entry in the receive FIFO (pointed to by the current FIFO write pointer).

When **SSIDR** is written to, the entry in the transmit FIFO (pointed to by the write pointer) is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. It is loaded into the transmit serial shifter, then serially shifted out onto the SSITx pin at the programmed bit rate.

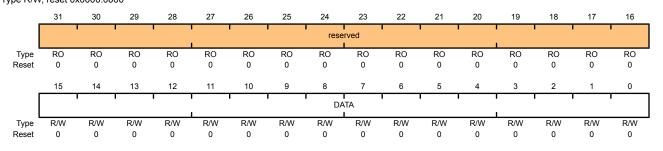

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

When the SSI is programmed for MICROWIRE frame format, the default size for transmit data is eight bits (the most significant byte is ignored). The receive data size is controlled by the programmer. The transmit FIFO and the receive FIFO are not cleared even when the SSE bit in the **SSICR1** register is set to zero. This allows the software to fill the transmit FIFO before enabling the SSI.

31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	DATA	R/W	0x0000	SSI Receive/Transmit Data

Dogorintion

A read operation reads the receive FIFO. A write operation writes the transmit FIFO.

Software must right-justify data when the SSI is programmed for a data size that is less than 16 bits. Unused bits at the top are ignored by the transmit logic. The receive logic automatically right-justifies the data.

Register 4: SSI Status (SSISR), offset 0x00C

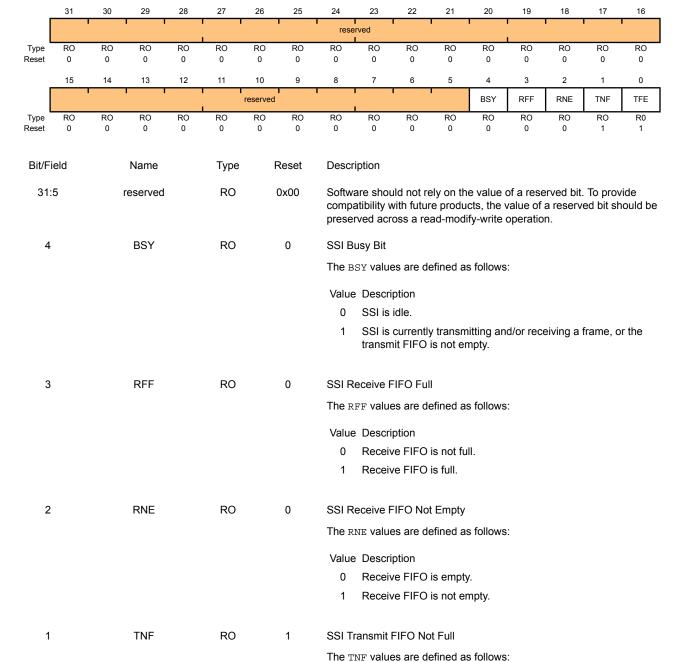

SSISR is a status register that contains bits that indicate the FIFO fill status and the SSI busy status.

SSI Status (SSISR)

SSI0 base: 0x4000.8000

Offset 0x00C

Type RO, reset 0x0000.0003

Value Description

Transmit FIFO is full.

Transmit FIFO is not full.

Bit/Field	Name	Туре	Reset	Description
0	TFE	R0	1	SSI Transmit FIFO Empty
				The ${\tt TFE}$ values are defined as follows:
				Value Description
				0 Transmit FIFO is not empty.
				1 Transmit FIFO is empty.

Register 5: SSI Clock Prescale (SSICPSR), offset 0x010

SSICPSR is the clock prescale register and specifies the division factor by which the system clock must be internally divided before further use.

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

SSI Clock Prescale (SSICPSR)

SSI0 base: 0x4000.8000 Offset 0x010

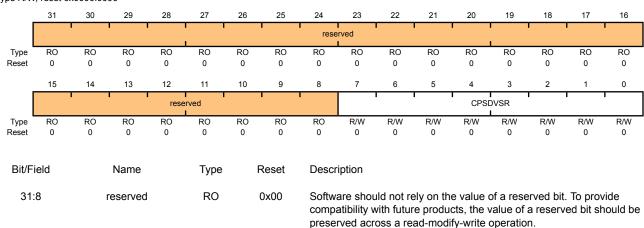

7:0

CPSDVSR

R/W

0x00

Type R/W, reset 0x0000.0000

SSI Clock Prescale Divisor

This value must be an even number from 2 to 254, depending on the frequency of SSIC1k. The LSB always returns 0 on reads.

Register 6: SSI Interrupt Mask (SSIIM), offset 0x014

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared to 0 on reset.

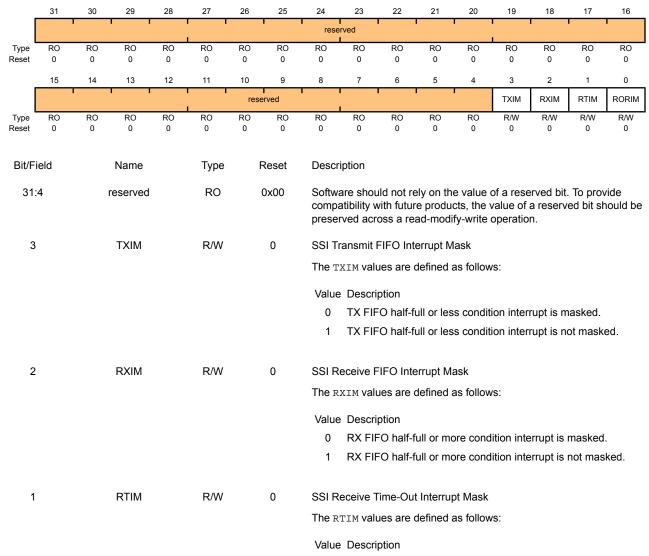

On a read, this register gives the current value of the mask on the relevant interrupt. A write of 1 to the particular bit sets the mask, enabling the interrupt to be read. A write of 0 clears the corresponding mask.

SSI Interrupt Mask (SSIIM)

SSI0 base: 0x4000.8000

Offset 0x014

Type R/W, reset 0x0000.0000

RX FIFO time-out interrupt is masked. RX FIFO time-out interrupt is not masked.

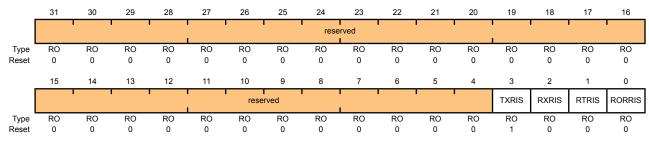

Bit/Field	Name	Туре	Reset	Description
0	RORIM	R/W	0	SSI Receive Overrun Interrupt Mask
				The RORIM values are defined as follows:
				Value Description
				0 RX FIFO overrun interrupt is masked.
				1 RX FIFO overrun interrupt is not masked.

Register 7: SSI Raw Interrupt Status (SSIRIS), offset 0x018

The SSIRIS register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

SSI Raw Interrupt Status (SSIRIS)

SSI0 base: 0x4000.8000 Offset 0x018 Type RO, reset 0x0000.0008

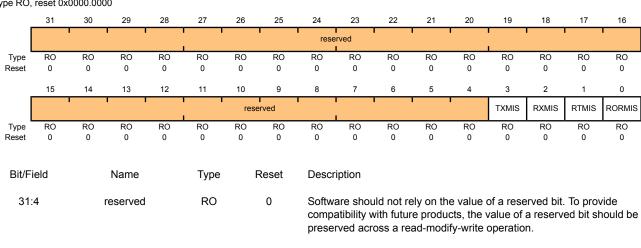

Bit/Field	Name	Туре	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TXRIS	RO	1	SSI Transmit FIFO Raw Interrupt Status Indicates that the transmit FIFO is half full or less, when set.
2	RXRIS	RO	0	SSI Receive FIFO Raw Interrupt Status Indicates that the receive FIFO is half full or more, when set.
1	RTRIS	RO	0	SSI Receive Time-Out Raw Interrupt Status Indicates that the receive time-out has occurred, when set.
0	RORRIS	RO	0	SSI Receive Overrun Raw Interrupt Status Indicates that the receive FIFO has overflowed, when set.

Register 8: SSI Masked Interrupt Status (SSIMIS), offset 0x01C

The **SSIMIS** register is the masked interrupt status register. On a read, this register gives the current masked status value of the corresponding interrupt. A write has no effect.

SSI Masked Interrupt Status (SSIMIS)

SSI0 base: 0x4000.8000 Offset 0x01C Type RO, reset 0x0000.0000

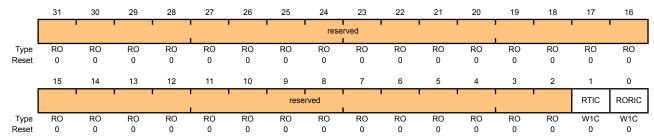

Register 9: SSI Interrupt Clear (SSIICR), offset 0x020

The SSIICR register is the interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

SSI Interrupt Clear (SSIICR)

SSI0 base: 0x4000.8000 Offset 0x020 Type W1C, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description

14 Inter-Integrated Circuit (I²C) Interface

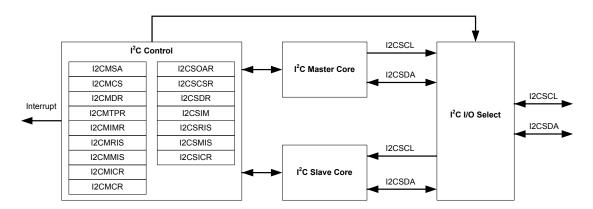

The Inter-Integrated Circuit (I^2C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I^2C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I^2C bus may also be used for system testing and diagnostic purposes in product development and manufacture. The LM3S2432 microcontroller includes one I^2C module, providing the ability to interact (both send and receive) with other I^2C devices on the bus.

Devices on the I²C bus can be designated as either a master or a slave. The Stellaris[®] I²C module supports both sending and receiving data as either a master or a slave, and also supports the simultaneous operation as both a master and a slave. There are a total of four I²C modes: Master Transmit, Master Receive, Slave Transmit, and Slave Receive. The Stellaris[®] I²C module can operate at two speeds: Standard (100 Kbps) and Fast (400 Kbps).

Both the I²C master and slave can generate interrupts; the I²C master generates interrupts when a transmit or receive operation completes (or aborts due to an error) and the I²C slave generates interrupts when data has been sent or requested by a master.

14.1 Block Diagram

Figure 14-1. I²C Block Diagram

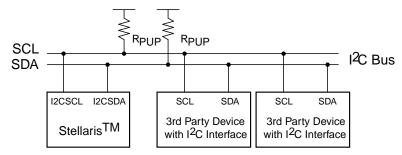

14.2 Functional Description

The I²C module is comprised of both master and slave functions which are implemented as separate peripherals. For proper operation, the SDA and SCL pins must be connected to bi-directional open-drain pads. A typical I²C bus configuration is shown in Figure 14-2 on page 348.

See "I²C" on page 489 for I²C timing diagrams.

Figure 14-2. I²C Bus Configuration

14.2.1 I²C Bus Functional Overview

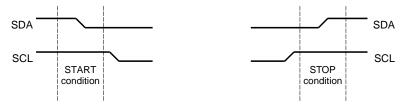

The I²C bus uses only two signals: SDA and SCL, named I2CSDA and I2CSCL on Stellaris[®] microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are high.

Every transaction on the I²C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in "START and STOP Conditions" on page 348) is unrestricted, but each byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

14.2.1.1 START and STOP Conditions

The protocol of the I²C bus defines two states to begin and end a transaction: START and STOP. A high-to-low transition on the SDA line while the SCL is high is defined as a START condition, and a low-to-high transition on the SDA line while SCL is high is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 14-3 on page 348.

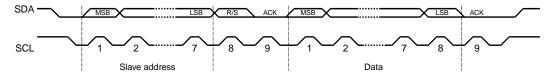

Figure 14-3. START and STOP Conditions

14.2.1.2 Data Format with 7-Bit Address

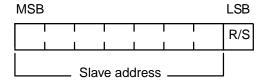

Data transfers follow the format shown in Figure 14-4 on page 349. After the START condition, a slave address is sent. This address is 7-bits long followed by an eighth bit, which is a data direction bit (\mathbb{R}/\mathbb{S} bit in the **I2CMSA** register). A zero indicates a transmit operation (send), and a one indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive/send formats are then possible within a single transfer.

Figure 14-4. Complete Data Transfer with a 7-Bit Address

The first seven bits of the first byte make up the slave address (see Figure 14-5 on page 349). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master will write (send) data to the selected slave, and a one in this position means that the master will receive data from the slave.

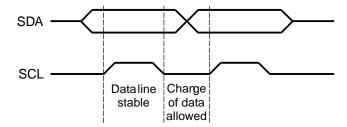

Figure 14-5. R/S Bit in First Byte

14.2.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is low (see Figure 14-6 on page 349).

Figure 14-6. Data Validity During Bit Transfer on the I²C Bus

14.2.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data sent out by the receiver during the acknowledge cycle must comply with the data validity requirements described in "Data Validity" on page 349.

When a slave receiver does not acknowledge the slave address, SDA must be left high by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Since the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

14.2.1.5 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is high. During arbitration, the first of the competing master devices to place a '1' (high) on SDA while another master transmits a '0' (low) will switch off its data output stage and retire until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

14.2.2 Available Speed Modes

The I²C clock rate is determined by the parameters: CLK_PRD, TIMER_PRD, SCL_LP, and SCL_HP.

where:

CLK_PRD is the system clock period

SCL_LP is the low phase of SCL (fixed at 6)

SCL HP is the high phase of SCL (fixed at 4)

TIMER_PRD is the programmed value in the I²C Master Timer Period (I2CMTPR) register (see page 367).

The I²C clock period is calculated as follows:

```
SCL PERIOD = 2*(1 + TIMER PRD)*(SCL LP + SCL HP)*CLK PRD
```

For example:

```
CLK_PRD = 50 ns
TIMER_PRD = 2
SCL_LP=6
SCL_HP=4
```

yields a SCL frequency of:

```
1/T = 333 \text{ Khz}
```

Table 14-1 on page 350 gives examples of timer period, system clock, and speed mode (Standard or Fast).

Table 14-1. Examples of I²C Master Timer Period versus Speed Mode

System Clock	Timer Period	Standard Mode	Timer Period	Fast Mode
4 Mhz	0x01	100 Kbps	-	-
6 Mhz	0x02	100 Kbps	-	-
12.5 Mhz	0x06	89 Kbps	0x01	312 Kbps
16.7 Mhz	0x08	93 Kbps	0x02	278 Kbps
20 Mhz	0x09	100 Kbps	0x02	333 Kbps
25 Mhz	0x0C	96.2 Kbps	0x03	312 Kbps
33Mhz	0x10	97.1 Kbps	0x04	330 Kbps
40Mhz	0x13	100 Kbps	0x04	400 Kbps

System Clock	Timer Period	Standard Mode	Timer Period	Fast Mode
50Mhz	0x18	100 Kbps	0x06	357 Kbps

14.2.3 Interrupts

The I²C can generate interrupts when the following conditions are observed:

- Master transaction completed
- Master transaction error
- Slave transaction received
- Slave transaction requested

There is a separate interrupt signal for the I²C master and I²C modules. While both modules can generate interrupts for multiple conditions, only a single interrupt signal is sent to the interrupt controller.

14.2.3.1 I²C Master Interrupts

The I²C master module generates an interrupt when a transaction completes (either transmit or receive), or when an error occurs during a transaction. To enable the I²C master interrupt, software must write a '1' to the I²C Master Interrupt Mask (I2CMIMR) register. When an interrupt condition is met, software must check the ERROR bit in the I²C Master Control/Status (I2CMCS) register to verify that an error didn't occur during the last transaction. An error condition is asserted if the last transaction wasn't acknowledge by the slave or if the master was forced to give up ownership of the bus due to a lost arbitration round with another master. If an error is not detected, the application can proceed with the transfer. The interrupt is cleared by writing a '1' to the I²C Master Interrupt Clear (I2CMICR) register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the I^2C Master Raw Interrupt Status (I2CMRIS) register.

14.2.3.2 I²C Slave Interrupts

The slave module generates interrupts as it receives requests from an I^2C master. To enable the I^2C slave interrupt, write a '1' to the I^2C Slave Interrupt Mask (I2CSIMR) register. Software determines whether the module should write (transmit) or read (receive) data from the I^2C Slave Data (I2CSDR) register, by checking the RREQ and TREQ bits of the I^2C Slave Control/Status (I2CSCSR) register. If the slave module is in receive mode and the first byte of a transfer is received, the FBR bit is set along with the RREQ bit. The interrupt is cleared by writing a '1' to the I^2C Slave Interrupt Clear (I2CSICR) register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the I²C Slave Raw Interrupt Status (I2CSRIS) register.

14.2.4 Loopback Operation

The I^2C modules can be placed into an internal loopback mode for diagnostic or debug work. This is accomplished by setting the LPBK bit in the I^2C Master Configuration (I2CMCR) register. In loopback mode, the SDA and SCL signals from the master and slave modules are tied together.

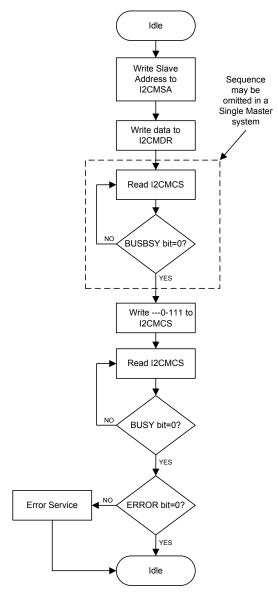

14.2.5 Command Sequence Flow Charts

This section details the steps required to perform the various I^2C transfer types in both master and slave mode.

14.2.5.1 I²C Master Command Sequences

The figures that follow show the command sequences available for the $\ensuremath{\text{I}}^2\ensuremath{\text{C}}$ master.

14.2.5.2 I²C Slave Command Sequences

Figure 14-13 on page 358 presents the command sequence available for the I²C slave.

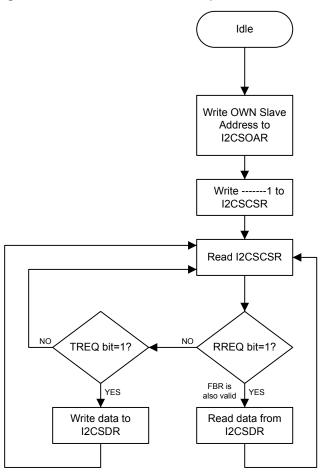

Figure 14-13. Slave Command Sequence

14.3 Initialization and Configuration

The following example shows how to configure the I^2C module to send a single byte as a master. This assumes the system clock is 20 MHz.

- 1. Enable the I²C clock by writing a value of 0x0000.1000 to the **RCGC1** register in the System Control module.
- Enable the clock to the appropriate GPIO module via the RCGC2 register in the System Control module.
- 3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. Also, be sure to enable the same pins for Open Drain operation.
- 4. Initialize the I²C Master by writing the **I2CMCR** register with a value of 0x0000.0020.
- 5. Set the desired SCL clock speed of 100 Kbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

```
TPR = (System Clock / (2 * (SCL_LP + SCL_HP) * SCL_CLK)) - 1;

TPR = (20MHz / (2 * (6 + 4) * 100000)) - 1;

TPR = 9
```

Write the **I2CMTPR** register with the value of 0x0000.0009.

- 6. Specify the slave address of the master and that the next operation will be a Send by writing the **I2CMSA** register with a value of 0x0000.0076. This sets the slave address to 0x3B.
- Place data (byte) to be sent in the data register by writing the I2CMDR register with the desired data.
- 8. Initiate a single byte send of the data from Master to Slave by writing the **I2CMCS** register with a value of 0x0000.0007 (STOP, START, RUN).
- 9. Wait until the transmission completes by polling the I2CMCS register's BUSBSY bit until it has been cleared.

14.4 I²C Register Map

Table 14-2 on page 359 lists the I^2C registers. All addresses given are relative to the I^2C base addresses for the master and slave:

- I²C Master 0: 0x4002.0000
- I²C Slave 0: 0x4002.0800

14.5 Register Descriptions (I²C Master)

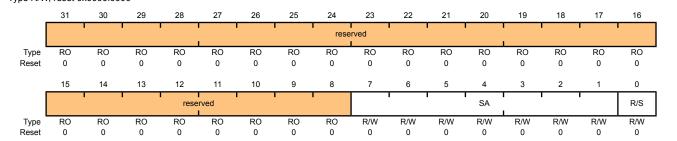

The remainder of this section lists and describes the I^2C master registers, in numerical order by address offset. See also "Register Descriptions (I2C Slave)" on page 373.

Register 1: I²C Master Slave Address (I2CMSA), offset 0x000

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Send (Low).

I2C Master Slave Address (I2CMSA)

I2C Master 0 base: 0x4002.0000 Offset 0x000 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:1	SA	R/W	0	I ² C Slave Address This field specifies bits A6 through A0 of the slave address.
0	R/S	R/W	0	Receive/Send

The \mathbb{R}/\mathbb{S} bit specifies if the next operation is a Receive (High) or Send (Low).

Value Description

0 Send.

1 Receive.

Register 2: I²C Master Control/Status (I2CMCS), offset 0x004

This register accesses four control bits when written, and accesses seven status bits when read.

The status register consists of seven bits, which when read determine the state of the I²C bus controller.

The control register consists of four bits: the RUN, START, STOP, and ACK bits. The START bit causes the generation of the START, or REPEATED START condition.

The STOP bit determines if the cycle stops at the end of the data cycle, or continues on to a burst. To generate a single send cycle, the I²C Master Slave Address (I2CMSA) register is written with the desired address, the R/S bit is set to 0, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due an error), the interrupt pin becomes active and the data may be read from the I2CMDR register. When the I²C module operates in Master receiver mode, the ACK bit must be set normally to logic 1. This causes the I²C bus controller to send an acknowledge automatically after each byte. This bit must be reset when the I²C bus controller requires no further data to be sent from the slave transmitter.

This field specifies bits A6 through A0 of the slave address.

Register 11: I²C Slave Control/Status (I2CSCSR), offset 0x004

This register accesses one control bit when written, and three status bits when read.

The read-only Status register consists of three bits: the FBR, RREQ, and TREQ bits. The First Byte Received (FBR) bit is set only after the Stellaris device detects its own slave address and receives the first data byte from the I^2C master. The Receive Request (RREQ) bit indicates that the Stellaris I^2C device has received a data byte from an I^2C master. Read one data byte from the I^2C Slave Data (I2CSDR) register to clear the RREQ bit. The Transmit Request (TREQ) bit indicates that the Stellaris I^2C device is addressed as a Slave Transmitter. Write one data byte into the I^2C Slave Data (I2CSDR) register to clear the TREQ bit.

The write-only Control register consists of one bit: the DA bit. The DA bit enables and disables the Stellaris $^{\circ}$ I²C slave operation.

15 Controller Area Network (CAN) Module

15.1 Controller Area Network Overview

Controller Area Network (CAN) is a multicast shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths below 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 m).

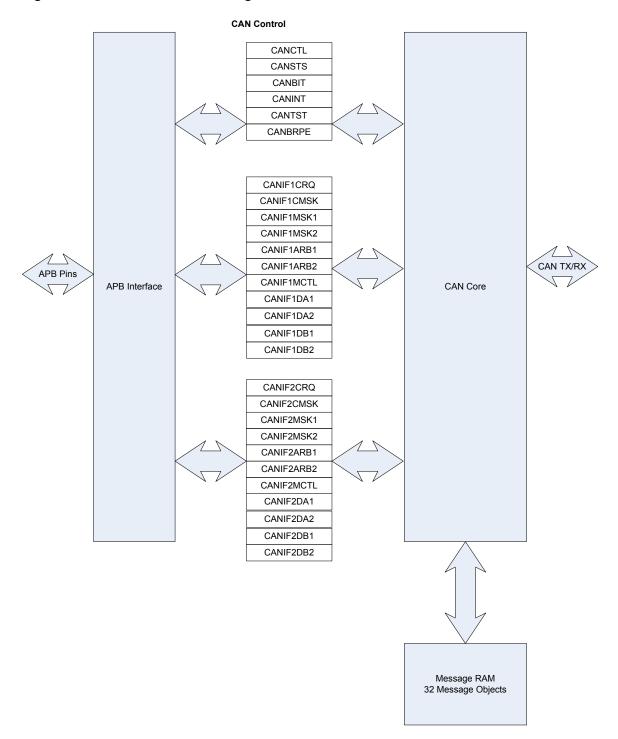

15.2 Controller Area Network Features

The Stellaris[®] CAN module supports the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects
- Each message object has its own identifier mask
- Maskable interrupt
- Disable Automatic Retransmission mode for Time Triggered CAN (TTCAN) applications
- Programmable Loopback mode for self-test operation
- Programmable FIFO mode
- Gluelessly attach to an external CAN PHY through the CANOTX and CANORX pins

15.3 Controller Area Network Block Diagram

Figure 15-1. CAN Module Block Diagram

15.4 Controller Area Network Functional Description

The CAN module conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These are accessed via the CAN message object register interface. The message memory is not directly accessable in the Stellaris[®] memory map, so the Stellaris[®] CAN controller provides an interface to communicate with the message memory.

The CAN message object register interface provides two register sets for communicating with the message objects. Since there is no direct access to the message object memory, these two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that needs to be processed.

15.4.1 Initialization

The software initialization is started by setting the INIT bit in the **CAN Control (CANCTL)** register, with software or by a hardware reset, or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While INIT is set, all message transfers to and from the CAN bus are stopped and the status of the CAN transmit output is recessive (High). Entering the initialization state does not change the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible when in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, it is sufficient to set it as not valid by clearing the MsgVal bit in the **CANIFnARB2** register. Otherwise, the whole message object has to be initialized, as the fields of the message object may not have valid information causing unexpected results. Access to the **CAN Bit Timing (CANBIT)** register and to the **CAN Baud Rate Prescalar Extension (CANBRPE)** register to configure the bit timing are enabled when both the INIT and CCE bits in the **CANCTL** register are set. To leave the initialization state, the INIT bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus Idle) before it takes part in bus activities and starts message transfers. The initialization of the message objects is independent of being in the initialization state and can be done on the fly, but message objects should all be configured to particular identifiers or set to not valid before the BSP starts the message transfer. To change the configuration of a message object during normal operation, set the MsgVal bit in the **CANIFnARB2** register to 0 (not valid). When the configuration is completed, MsgVal is set to 1 again (valid).

15.4.2 Operation

Once the CAN module is initialized and the INIT bit in the **CANCTL** register is reset to 0, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As messages are received, they are stored in their appropriate message objects if they pass the message handler's filtering. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the Msk bits in the **CANIFnMSKn** registers) is used, the arbitration bits which are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message any time via the CAN Interface Registers (CANIFnCRQ, CANIFnCMSK, CANIFnMSKn, CANIFnARBn, CANIFnMCTL, CANIFnDAn, and CANIFnDBn). The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects are under the control of the software that is managing the CAN hardware. These can be message objects used for one-time data transfers, or permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. To start the transmission, the \mathtt{TxRqst} bit in the **CANTXRQn** register and the \mathtt{NewDat} bit in the **CANNWDAn** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier for the message object. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started. Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

There are two sets of CAN Interface Registers (**CANIF1x** and **CANIF2x**), which are used to access the Message Objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The function of the two sets are independent and identical and can be used to gueue transactions.

15.4.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if there is no data transfer between the CAN Interface Registers and message RAM, the valid message object with the highest priority and that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's NewDat bit is reset and can be viewed in the CANNWDAn register. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the TxRqst bit in the CANIFnCMSK register is reset. If the TxIE bit in the CANIFnMCTL register is set, the IntPnd bit in the CANIFnMCTL register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

15.4.4 Configuring a Transmit Message Object

Table 15-1 on page 386 specifies the bit settings for a transmit message object.

Table 15-1. Transmit Message Object Bit Settings

Register	CANIFnARB2	CAI	NIFnC	MSK	CANIFnMCTL	CANIFnARB2	CANIFnMCTL						
Bit	MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
Value	1	appl	appl	appl	1	1	0	0	0	appl	0	appl	0

The Xtd and ID bit fields in the **CANIFnARBn** registers are set by an application. They define the identifier and type of the outgoing message. If an 11-bit Identifier (Standard Frame) is used, it is programmed to bits [28:18] of **CANIFnARB1**, as bits 17:0 of **CANIFnARBn** are not used by the CAN controller for 11-bit identifiers.

If the TxIE bit is set, the IntPnd bit is set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received Remote Frame causes the TxRqst bit to be set and the Remote Frame is autonomously answered by a Data Frame with the data from the message object.

The DLC bit in the **CANIFnMCTL** register is set by an application. TxRqst and RmtEn may not be set before the data is valid.

The CAN mask registers (Msk bits in CANIFnMSKn, UMask bit in CANIFnMCTL register, and MXtd and MDir bits in CANIFnMSK2 register) may be used (UMask=1) to allow groups of Remote Frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked.

15.4.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the MsgVal nor the TxRqst bits have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn** or **CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the **CANIFnDAn** or **CANIFnDBn** register or the message object is transferred to the **CANIFnDAn** or **CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the WR, NewDat, DataA, and DataB bits are written to the CAN IFn Command Mask (CANIFnMSKn) register, followed by writing the CAN IFn Data registers, and then the number of the message object is written to the CAN IFn Command Request (CANIFnCRQ) register, to update the data bytes and the TxRqst bit at the same time.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst. When NewDat is set together with TxRqst, NewDat is reset as soon as the new transmission has started.

15.4.6 Accepting Received Message Objects

When the arbitration and control field (ID + Xtd + RmtEn + DLC) of an incoming message is completely shifted into the CAN module, the message handling capability of the module starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the Acceptance Filtering unit is loaded with the arbitration bits from the core. Then the arbitration and mask fields (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the Acceptance Filtering unit and compared with the arbitration field from the shift register. This is repeated with each following message object until a matching message object is found or until the end of the message RAM is reached. If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of frame received.

15.4.7 Receiving a Data Frame

The message handler stores the message from the CAN module receive shift register into the respective message object in the message RAM. It stores the data bytes, all arbitration bits, and the Data Length Code into the corresponding message object. This is implemented to keep the data bytes connected with the identifier even if arbitration mask registers are used. The CANIFNMCTL.NewDat bit is set to indicate that new data has been received. The CPU should reset CANIFNMCTL.NewDat when it reads the message object to indicate to the controller that the message has been received and the buffer is free to receive more messages. If the CAN controller receives a message and the CANIFNMCTL.NewDat bit was already set, the MsgLst bit is set to indicate that the previous data was lost. If the CANIFNMCTL.RxIE bit is set, the CANIFNMCTL.IntPnd bit is set, causing the CANIFNMCTL.RxIE bit is set, the message object that just received a message. The CANIFNMCTL.TxRqst bit of this message object is reset to prevent the transmission of a Remote Frame, while the requested Data Frame has just been received.

15.4.8 Receiving a Remote Frame

When a Remote Frame is received, three different configurations of the matching message object have to be considered:

Dir = 1 (direction = transmit), RmtEn = 1, UMask = 1 or 0

At the reception of a matching Remote Frame, the TxRqst bit of this message object is set. The rest of the message object remains unchanged.

Dir = 1 (direction = transmit), RmtEn = 0, UMask = 0

At the reception of a matching Remote Frame, the TxRqst bit of this message object remains unchanged; the Remote Frame is ignored. This remote frame is disabled and will not automatically respond or indicate that the remote frame ever happened.

Dir = 1 (direction = transmit), RmtEn = 0, UMask = 1

At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control field (ID + Xtd + RmtEn + DLC) from the shift register is stored into the message object in the message RAM and the NewDat bit of this message object is set. The data field of the message object remains unchanged; the Remote Frame is treated similar to a received Data Frame. This is useful for a remote data request from another CAN device for which the Stellaris® controller does not have readily available data. The software must fill the data and answer the frame manually.

15.4.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message object with the lowest message number. This should not be confused with the message identifier as that priority is enforced by the CAN bus. This means that if message object 1 and message object 2 both have valid messages that need to be transmitted, message object 1 will always be transmitted first regardless of the message identifier in the message object itself.

15.4.10 Configuring a Receive Message Object

Table 15-2 on page 388 specifies the bit settings for a transmit message object.

Table 15-2. Receive Message Object Bit Settings

	Register	CANIFnARB2	CANIFnCMSK		MSK	CANIFnMCTL	CANIFnARB2	2 CANIFnMCTL						
	Bit	MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
ľ	Value	1	appl	appl	appl	1	0	0	0	appl	0	0	0	0

The Xtd and ID bit fields in the **CANIFnARBn** registers are set by an application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used, it is programmed to bits [28:18] of **CANIFnARB1**, and bits [17:0] are ignored by the CAN controller. When a Data Frame with an 11-bit Identifier is received, bits [17:0] are set to 0.

If the RxIE bit is set, the IntPnd bit is set when a received Data Frame is accepted and stored in the message object.

When the message handler stores a Data Frame in the message object, it stores the received Data Length Code and eight data bytes. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by nonspecified values.

The CAN mask registers (Msk bits in **CANIFnMSKn**, UMask bit in **CANIFnMCTL** register, and MXtd and MDir bits in **CANIFnMSK2** register) may be used (UMask=1) to allow groups of Data Frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications.

15.4.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes 0x007F to the CAN IFn Command Mask (CANIFnCMSK) register and then writes the number of the message object to the CAN IFn Command Request (CANIFnCRQ) register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (CANIFnMSKn, CANIFnARBn, and CANIFnMCTL). Additionally, the NewDat and IntPnd bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt being generated by this message object.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the matching messages has been received.

The actual value of NewDat shows whether a new message has been received since the last time this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time this message object was read. MsgLst is not automatically reset.

Using a Remote Frame, the CPU may request new data from another CAN node on the CAN bus. Setting the \mathtt{TxRqst} bit of a receive object causes the transmission of a Remote Frame with the receive object's identifier. This Remote Frame triggers the other CAN node to start the transmission of the matching Data Frame. If the matching Data Frame is received before the Remote Frame could be transmitted, the \mathtt{TxRqst} bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data, slightly earlier than expected.

15.4.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. An interrupt remains pending until the CPU has cleared it.

The Status Interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. A message interrupt is cleared by clearing the message object's IntPnd bit. The Status Interrupt is cleared by reading the **CAN Status** (**CANSTS**) register.

The interrupt identifier IntId in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register holds the value to 0. If the value of **CANINT** is different from 0, then there is an interrupt pending. If the IE bit is set in the **CANCTL** register, the interrupt line to the CPU is active. The interrupt line remains active until **CANINT** is 0, all interrupt sources have been cleared, (the cause of the interrupt is reset), or until IE is reset, which disables interrupts from the CAN controller.

The value 0x8000 in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register (Error Interrupt or Status Interrupt). This indicates that there is either a new Error Interrupt or a new Status Interrupt. A write access can clear the RxOK, TxOK, and LEC flags in the **CANSTS** register, however, only a read access to the **CANSTS** register will clear the source of the status interrupt.

IntId points to the pending message interrupt with the highest interrupt priority. The SIE bit in the **CANCTL** register controls whether a change of the status register may cause an interrupt. The EIE bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the microcontroller's interrupt controller. The **CANINT** interrupt register is updated even when the IE bit is set to zero.

There are two possibilities when handling the source of a message interrupt. The first is to read the IntId bit in the **CANINT** interrupt register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and reset the message object's IntPnd at the same time by setting the ClrIntPnd bit in the CAN IFn Command Mask (CANIFnCMSK) register. When the IntPnd bit is cleared, the CANINT register will contain the message number for the next message object with a pending interrupt.

15.4.13 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

15.4.14 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations

remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 15-2 on page 390): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 15-3 on page 390). The length of the time quantum (tq), which is the basic time unit of the bit time, is defined by the CAN controller's system clock (fsys) and the Baud Rate Prescaler (grap):

The CAN module's system clock fsys is the frequency of its CAN module clock (CAN_CLK) input.

The Synchronization Segment $\operatorname{Sync_Seg}$ is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of $\operatorname{Sync_Seg}$ and the $\operatorname{Sync_Seg}$ is called the *phase error* of that edge.

The Propagation Time Segment Prop_Seg is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments Phase_Seg1 and Phase_Seg2 surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Figure 15-2. CAN Bit Time

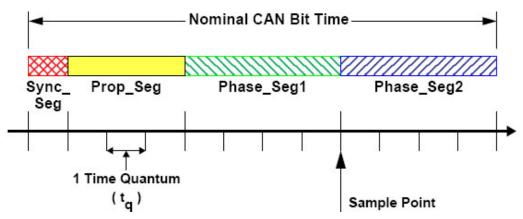

Table 15-3. CAN Protocol Ranges^a

Parameter	Range	Remark
BRP	[1 32]	Defines the length of the time quantum t _q
Sync_Seg	1 t _q	Fixed length, synchronization of bus input to system clock
Prop_Seg	[1 8] t _q	Compensates for the physical delay times
Phase_Seg1	[1 8] t _q	May be lengthened temporarily by synchronization
Phase_Seg2	[1 8] t _q	May be shortened temporarily by synchronization

Parameter	Range	Remark
SJW	[1 4] t _q	May not be longer than either Phase Buffer Segment

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, and SJW and BRP are combined in the other byte.

In these bit timing registers, the four components TSEG1, TSEG2, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits. Therefore, the length of the bit time is (programmed values):

```
[TSEG1 + TSEG2 + 3] tq
or (functional values):
[Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq
```

The data in the bit timing registers are the configuration input of the CAN protocol controller. The Baud Rate Prescalar (configured by BRP) defines the length of the time quantum, the basic time unit of the bit time; the Bit Timing Logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the Sample Point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the Sample Point and processes the sampled bus input bit. The time after the Sample Point that is needed to calculate the next bit to be sent (that is, the data bit, CRC bit, stuff bit, error flag, or idle) is called the Information Processing Time (IPT).

The IPT is application-specific but may not be longer than 2 tq; the CAN's IPT is 0 tq. Its length is the lower limit of the programmed length of Phase_Seg2. In case of synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

15.4.15 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is the $Prop_Seg$. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for $Prop_Seg$ is converted into time quanta (rounded up to the nearest integer multiple of tg).

The $Sync_Seg$ is 1 tq long (fixed), which leaves (bit time - $Prop_Seg$ - 1) tq for the two Phase Buffer Segments. If the number of remaining tq is even, the Phase Buffer Segments have the same length, that is, $Phase_Seg2$ = $Phase_Seg1$, else $Phase_Seg2$ = $Phase_Seg1$ + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than the CAN controller's Information Processing Time, which is, depending on the actual implementation, in the range of [0..2] tq.

The length of the Synchronization Jump Width is set to its maximum value, which is the minimum of 4 and Phase Seq1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

```
(1 - df) \times fnom <= fosc <= (1 + df) \times fnom
```

where:

- df = maximum tolerance of oscillator frequency
- fosc = actual oscillator frequency
- fnom = nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

```
df <= (Phase_Seg1,Phase_Seg2)min/ 2 x (13 x tbit - Phase_Seg2)
dfmax = 2 x df x fnom</pre>
```

where:

- Phase_Seg1 and Phase_Seg2 are from Table 15-3 on page 390
- tbit = Bit Time
- dfmax = maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

The resulting configuration is written into the CAN Bit Timing (CANBIT) register :

```
(Phase_Seg2-1)&(Phase_Seg1+Prop_Seg-1)&(SynchronizationJumpWidth-1)&(Prescaler-1)
```

15.4.15.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN_CLK is 10 MHz, BRP is 0, and the bit rate is 1 Mbps.

```
tq 100 ns = tCAN_CLK
delay of bus driver 50 ns
delay of receiver circuit 30 ns
delay of bus line (40m) 220 ns
```

```
tProp 600 ns = 6 × tq
tSJW 100 ns = 1 × tq
tTSeg1 700 ns = tProp + tSJW
tTSeg2 200 ns = Information Processing Time + 1 × tq
tSync-Seg 100 ns = 1 × tq
bit time 1000 ns = tSync-Seg + tTSeg1 + tTSeg2
tolerance for CAN_CLK 0.39 % =
    min(PB1,PB2)/ 2 × (13 x bit time - PB2) =
    0.1us/ 2 x (13x lus - 2us)
```

In the above example, the concatenated bit time parameters are (2-1)3&(7-1)4&(1-1)2&(1-1)6, and **CANBIT** is programmed to 0x1600.

15.4.15.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of CAN_CLK is 2 MHz, BRP is 1, and the bit rate is 100 Kbps.

```
tq 1 ms = 2 x tCAN_CLK
delay of bus driver 200 ns
delay of receiver circuit 80 ns
delay of bus line (40m) 220 ns
tProp 1 ms = 1 x tq
tSJW 4 ms = 4 x tq
tTSeg1 5 ms = tProp + tSJW
tTSeg2 4 ms = Information Processing Time + 3 x tq
tSync-Seg 1 ms = 1 x tq
bit time 10 ms = tSync-Seg + tTSeg1 + tTSeg2
tolerance for CAN_CLK 1.58 % =
   min(PB1,PB2)/ 2 x (13 x bit time - PB2) =
   4us/ 2 x (13 x 10us - 4us)
```

In this example, the concatenated bit time parameters are (4-1)3&(5-1)4&(4-1)2&(2-1)6, and **CANBIT** is programmed to 0x34C1.

15.5 Controller Area Network Register Map

Table 15-4 on page 393 lists the registers. All addresses given are relative to the CAN base address of:

CAN0: 0x4004.0000

All accesses are on word (32-bit) boundaries.

Table 15-4. CAN Register Map

Offset	Name	Туре	Reset	Description	See page
0x000	CANCTL	R/W	0x0000.0001	CAN Control	396

15.6 Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers which are used to access the Message Objects in the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

Register 1: CAN Control (CANCTL), offset 0x000

26

25

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or resetting INIT. If the device goes bus-off, it sets INIT, stopping all bus activities. Once INIT has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 * 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after INIT is reset, each time a sequence of 11 High bits has been monitored, a BitOError code is written to the **CANSTS** status register, enabling the CPU to readily check whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the proceeding of the bus-off recovery sequence.

Error Interrupt Enable

generates an interrupt.

0: Disabled. No Error Status interrupt is generated.

1: Enabled. A change in the Boff or EWarn bits in the CANSTS register

Bit/Field	Name	Туре	Reset	Description
2	SIE	R/W	0	Status Change Interrupt Enable
				0: Disabled. No Status Change interrupt is generated.
				1: Enabled. An interrupt is generated when a message has successfully been transmitted or received, or a CAN bus error has been detected. A change in the \mathtt{TxOk} or \mathtt{RxOk} bits in the CANSTS register generates an interrupt.
1	IE	R/W	0	CAN Interrupt Enable
				0: Interrupt disabled.
				1: Interrupt enabled.
0	INIT	R/W	1	Initialization
				0: Normal operation.
				1: Initialization started.

Register 2: CAN Status (CANSTS), offset 0x004

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared to 0 when a message has been transferred (reception or transmission) without error. The unused error code 7 may be written by the CPU to check for updates.

An Error Interrupt is generated by the BOff and EWarn bits and a Status Change Interrupt is generated by the RxOk, TxOk, and LEC bits, assuming that the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPass bit or a write to the RxOk, TxOk, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

0: The CAN module is in the Error Active state, that is, the receive or transmit error count is less than or equal to 127.

1: The CAN module is in the Error Passive state, that is, the receive or transmit error count is greater than 127.

Bit/Field	Name	Туре	Reset	Description
4	RxOK	R/W	0	Received a Message Successfully
				0: Since this bit was last reset to 0, no message has been successfully received.
				1: Since this bit was last reset to 0, a message has been successfully received, independent of the result of the acceptance filtering.
				This bit is never reset by the CAN module.
3	TxOK	R/W	0	Transmitted a Message Successfully
				0: Since this bit was last reset to 0, no message has been successfully transmitted.
				1: Since this bit was last reset to 0, a message has been successfully transmitted error-free and acknowledged by at least one other node.
				This bit is never reset by the CAN module.

Bit/Field	Name	Type	Reset	Description
2:0	LEC	R/W	0x0	Last Error Code

This is the type of the last error to occur on the CAN bus.

Value Definition 0x0 No Error 0x1 Stuff Error

More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.

0x2 Form Error

A fixed format part of the received frame has the wrong format.

0x3 ACK Error

The message transmitted was not acknowledged by another node.

0x4 Bit 1 Error

When a message is transmitted, the CAN controller monitors the data lines to detect any conflicts. When the arbitration field is transmitted, data conflicts are a part of the arbitration protocol. When other frame fields are transmitted, data conflicts are considered errors.

A Bit 1 Error indicates that the device wanted to send a High level (logical 1) but the monitored bus value was Low (logical 0).

0x5 Bit 0 Error

A Bit 0 Error indicates that the device wanted to send a Low level (logical 0) but the monitored bus value was High (logical 1)

During bus-off recovery, this status is set each time a sequence of 11 High bits has been monitored. This enables the CPU to monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus.

0x6 CRC Error

The CRC checksum was incorrect in the received message, indicating that the calculated value received did not match the calculated CRC of the data.

0x7 Unused

When the LEC bit shows this value, no CAN bus event was detected since the CPU wrote this value to LEC.

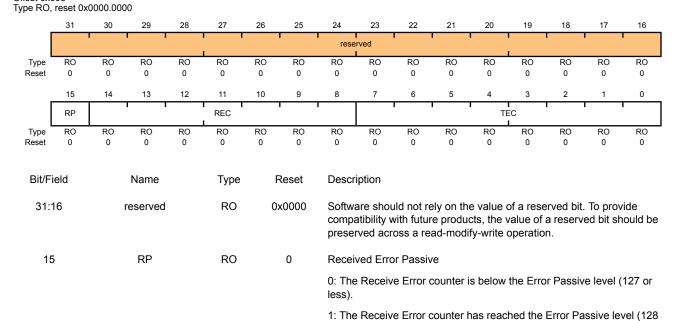

Register 3: CAN Error Counter (CANERR), offset 0x008

This register contains the error counter values, which can be used to analyze the cause of an error.

CAN Error Counter (CANERR)

CAN0 base: 0x4004.0000 Offset 0x008

14:8

or greater).

Receive Error Counter State of the receiver error counter (0 to 127).

7:0 TEC RO 0x0 Transmit Error Counter

RO

0x0

REC

State of the transmit error counter (0 to 255).

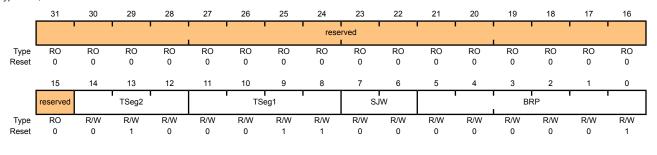

Register 4: CAN Bit Timing (CANBIT), offset 0x00C

This register is used to program the bit width and bit quantum. Values are to be programmed to the system clock frequency. This register is write-enabled by the CCE and INIT bits in the CANCTL register.

With a CAN module clock (CAN_CLK) of 8 MHz, the register reset value of 0x230 configures the CAN for a bit rate of 500 Kbps.

CAN Bit Timing (CANBIT)

CAN0 base: 0x4004.0000 Offset 0x00C Type R/W, reset 0x0000.2301

Bit/Field	Name	Туре	Reset	Description
31:15	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14:12	TSeg2	R/W	0x2	Time Segment after Sample Point
				0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
				So, for example, a reset value of 0x2 defines that there is 3(2+1) bit time quanta defined for Phase_Seg2 (see Figure 15-2 on page 390). The bit time quanta is defined by BRP.
11:8	TSeg1	R/W	0x3	Time Segment Before Sample Point
				0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
				So, for example, the reset value of 0x3 defines that there is 4(3+1) bit time quanta defined for Phase_Seg1 (see Figure 15-2 on page 390). The bit time quanta is define by BRP.
7:6	SJW	R/W	0x0	(Re)Synchronization Jump Width
				0.000 0.000. The patrial interpretation by the bandward of this value is

0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of TSeg2 or TSeg1 by the value in SJW. So the reset value of 0 adjusts the length by 1 bit time quanta.

Bit/Field	Name	Туре	Reset	Description
5:0	BRP	R/W	0x1	Baud Rate Prescalar
				0x00-0x03F: The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. BRP defines the number of CAN clock periods that make up 1 bit time
				quanta, so the reset value is 2 bit time quanta (1+1).
				The BRPRE register can be used to further divide the bit time.

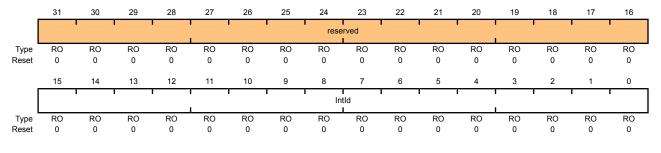

Register 5: CAN Interrupt (CANINT), offset 0x010

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. An interrupt remains pending until the CPU has cleared it. If the IntId bit is not 0x0000 (the default) and the IE bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the IntId bit is set back to 0x0000 when the cause of all interrupts are reset or until IE is reset.

CAN Interrupt (CANINT)

preserved across a read-modify-write operation.

Baud Rate Prescalar Extension.

Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020 Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080

This register is used to start a transfer when its MNUM bit field is updated. Its Busy bit indicates that the information is transferring from the CAN Interface Registers to the internal message RAM.

A message transfer is started as soon as there is a write of the message object number with the MNUM bit. With this write operation, the Busy bit is automatically set to 1 to indicate that a transfer is in progress. After a wait time of 3 to 6 CAN_CLK periods, the transfer between the interface register and the message RAM completes, which then sets the Busy bit back to 0.

				0: This message object is not waiting for transmission.
				1: The transmission of this message object is requested and is not yet done.
7	EoB	R/W	0x0	End of Buffer
				0: Message object belongs to a FIFO Buffer and is not the last message object of that FIFO Buffer.
				1: Single message object or last message object of a FIFO Buffer.
				This bit is used to concatenate two or more message objects (up to 32) to build a FIFO buffer. For a single message object (thus not belonging to a FIFO buffer), this bit must be set to 1.
6:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3:0	DLC	R/W	0x0	Data Length Code
				Value Description
				0x0-0x8 Specifies the number of bytes in the Data Frame.
				0x9-0xF Defaults to a Data Frame with 8 bytes.
				The DLC bit in the CANIFnMCTL register of a message object must be

November 30, 2007 417

defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame,

it writes \mathtt{DLC} to the value given by the received message.

Register 22: CAN IF1 Data A1 (CANIF1DA1), offset 0x03C

Register 23: CAN IF1 Data A2 (CANIF1DA2), offset 0x040

Register 24: CAN IF1 Data B1 (CANIF1DB1), offset 0x044

Register 25: CAN IF1 Data B2 (CANIF1DB2), offset 0x048

Register 26: CAN IF2 Data A1 (CANIF2DA1), offset 0x09C

Register 27: CAN IF2 Data A2 (CANIF2DA2), offset 0x0A0

Register 28: CAN IF2 Data B1 (CANIF2DB1), offset 0x0A4

Register 29: CAN IF2 Data B2 (CANIF2DB2), offset 0x0A8

These registers contain the data to be sent or that has been received. In a CAN Data Frame, data byte 0 is the first byte to be transmitted or received and data byte 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte is transmitted first.

CAN IF1 Data A1 (CANIF1DA1)

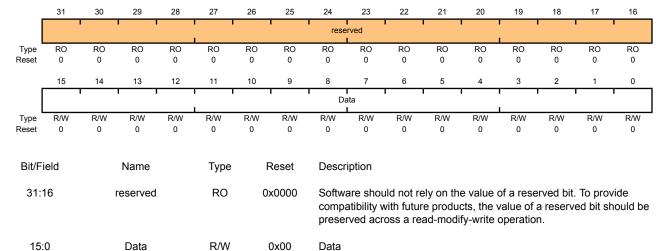

CAN0 base: 0x4004.0000

Offset 0x03C

Data

The CANIFnDA1 registers contain data bytes 1 and 0; CANIFnDA2 data bytes 3 and 2; CANIFnDB1 data bytes 5 and 4; and CANIFnDB2 data bytes 7 and 6.

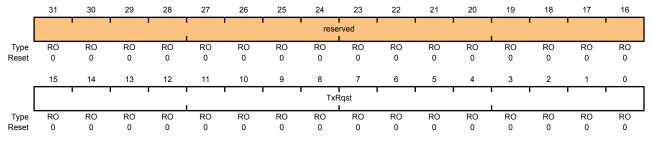

Register 30: CAN Transmission Request 1 (CANTXRQ1), offset 0x100 Register 31: CAN Transmission Request 2 (CANTXRQ2), offset 0x104

The **CANTXRQ1** and **CANTXRQ2** registers hold the \mathtt{TxRqst} bits of the 32 message objects. By reading out these bits, the CPU can check which message object has a transmission request pending. The \mathtt{TxRqst} bit of a specific message object can be changed by three sources: (1) the CPU via the **CAN IFn Message Control (CANIFnMCTL)** register, (2) the message handler state machine after the reception of a Remote Frame, or (3) the message handler state machine after a successful transmission.

The **CANTXRQ1** register contains the TxRqst bit of the first 16 message objects in the message RAM; the **CANTXRQ2** register contains the TxRqst bit of the second 16 message objects.

CAN Transmission Request 1 (CANTXRQ1)

(of all message objects)

^{0:} The message object is not waiting for transmission.

^{1:} The transmission of the message object is requested and is not yet done.

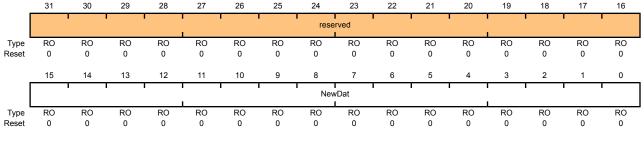

Register 32: CAN New Data 1 (CANNWDA1), offset 0x120 Register 33: CAN New Data 2 (CANNWDA2), offset 0x124

The **CANNWDA1** and **CANNWDA2** registers hold the NewDat bits of the 32 message objects. By reading these bits, the CPU can check which message object has its data portion updated. The NewDat bit of a specific message object can be changed by three sources: (1) the CPU via the **CAN IFN Message Control (CANIFNMCTL)** register, (2) the message handler state machine after the reception of a Data Frame, or (3) the message handler state machine after a successful transmission.

The **CANNWDA1** register contains the NewDat bit of the first 16 message objects in the message RAM; the **CANNWDA2** register contains the NewDat bit of the second 16 message objects.

(of all message objects)

^{0:} No new data has been written into the data portion of this message object by the message handler since the last time this flag was cleared by the CPU.

^{1:} The message handler or the CPU has written new data into the data portion of this message object.

Register 34: CAN Message 1 Interrupt Pending (CANMSG1INT), offset 0x140 Register 35: CAN Message 2 Interrupt Pending (CANMSG2INT), offset 0x144

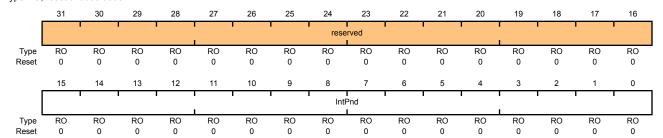

The **CANMSG1INT** and **CANMSG2INT** registers hold the IntPnd bits of the 32 message objects. By reading these bits, the CPU can check which message object has an interrupt pending. The IntPnd bit of a specific message object can be changed through two sources: (1) the CPU via the **CAN IFN Message Control (CANIFNMCTL)** register, or (2) the message handler state machine after the reception or transmission of a frame.

This field is also encoded in the CAN Interrupt (CANINT) register.

The **CANMSG1INT** register contains the IntPnd bit of the first 16 message objects in the message RAM; the **CANMSG2INT** register contains the IntPnd bit of the second 16 message objects.

^{0:} This message object is not configured and is ignored by the message handler.

^{1:} This message object is configured and should be considered by the message handler.

16 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages, and provides a logical output that signals the comparison result.

The LM3S2432 controller provides two independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

Note: Not all comparators have the option to drive an output pin. See the Comparator Operating Mode tables for more information.

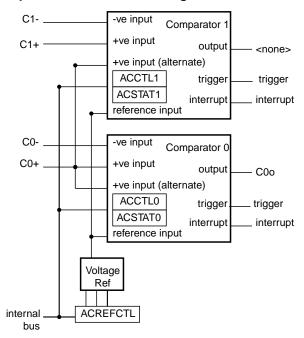

A comparator can compare a test voltage against any one of these voltages:

- An individual external reference voltage
- A shared single external reference voltage
- A shared internal reference voltage

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

16.1 Block Diagram

Figure 16-1. Analog Comparator Module Block Diagram

16.2 Functional Description

Important: It is recommended that the Digital-Input enable (the GPIODEN bit in the GPIO module) for the analog input pin be disabled to prevent excessive current draw from the I/O pads.

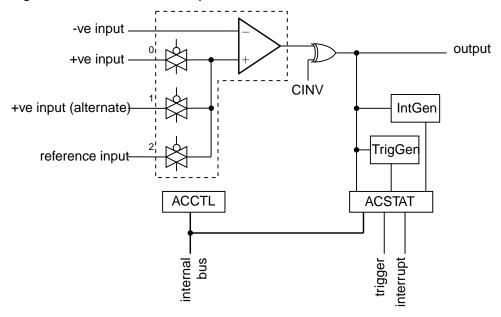

The comparator compares the VIN- and VIN+ inputs to produce an output, VOUT.

```
VIN- < VIN+, VOUT = 1

VIN- > VIN+, VOUT = 0
```

As shown in Figure 16-2 on page 424, the input source for VIN- is an external input. In addition to an external input, input sources for VIN+ can be the +ve input of comparator 0 or an internal reference.

Figure 16-2. Structure of Comparator Unit

A comparator is configured through two status/control registers (ACCTL and ACSTAT). The internal reference is configured through one control register (ACREFCTL). Interrupt status and control is configured through three registers (ACMIS, ACRIS, and ACINTEN). The operating modes of the comparators are shown in the Comparator Operating Mode tables.

Typically, the comparator output is used internally to generate controller interrupts. It may also be used to drive an external pin or generate an analog-to-digital converter (ADC) trigger.

Important: Certain register bit values must be set before using the analog comparators. The proper pad configuration for the comparator input and output pins are described in the Comparator Operating Mode tables.

Table 16-1. Comparator 0 Operating Modes

ACCNTL0	Com	Comparator 0									
ASRCP	VIN-	VIN+	Output	Interrupt	ADC Trigger						
00	C0-	C0+	C0o/C1+	yes	yes						
01	C0-	C0+	C0o/C1+	yes	yes						

ACCNTL0	Com	Comparator 0								
ASRCP	VIN-	VIN+	Output	Interrupt	ADC Trigger					
10	C0-	Vref	C0o/C1+	yes	yes					
11	C0-	reserved	C0o/C1+	yes	yes					

Table 16-2. Comparator 1 Operating Modes

ACCNTL1	Com	Comparator 1									
ASRCP	VIN-	VIN+	Output	Interrupt	ADC Trigger						
00	C1-	C0o/C1+ ^a	n/a	yes	yes						
01	C1-	C0+	n/a	yes	yes						
10	C1-	Vref	n/a	yes	yes						
11	C1-	reserved	n/a	yes	yes						

a. C0o and C1+ signals share a single pin and may only be used as one or the other.

16.2.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 16-3 on page 425. This is controlled by a single configuration register (**ACREFCTL**). Table 16-3 on page 425 shows the programming options to develop specific internal reference values, to compare an external voltage against a particular voltage generated internally.

Figure 16-3. Comparator Internal Reference Structure

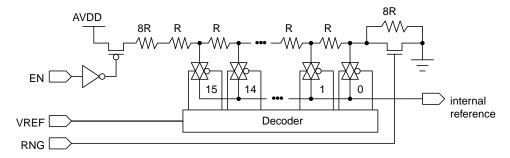

Table 16-3. Internal Reference Voltage and ACREFCTL Field Values

ACREFCTL Register		Output Reference Voltage Based on VREF Field Value
EN Bit Value	RNG Bit Value	
EN=0		0 V (GND) for any value of VREF; however, it is recommended that RNG=1 and VREF=0 for the least noisy ground reference.

ACREFCTL Register		Output Reference Voltage Based on VREF Field Value			
EN Bit Value	RNG Bit Value				
EN=1	RNG=0	Total resistance in ladder is 32 R.			
		$V_{REF} = AV_{DD} \times \frac{R_{VREF}}{R_{T}}$			
		$V_{REF} = AV_{DD} \times \frac{(VREF + 8)}{32}$			
		$V_{REF} = 0.825 + 0.103 \text{ VREF}$			
		The range of internal reference in this mode is 0.825-2.37 V.			
	RNG=1	Total resistance in ladder is 24 R.			
		$V_{REF} = AV_{DD} \times \frac{R_{VREF}}{R_{T}}$			
		$V_{REF} = AV_{DD} \times \frac{(VREF)}{24}$			
		$V_{REF} = 0.1375 \times V_{REF}$			
		The range of internal reference for this mode is 0.0-2.0625 V.			

16.3 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

- 1. Enable the analog comparator 0 clock by writing a value of 0x0010.0000 to the **RCGC1** register in the System Control module.
- 2. In the GPIO module, enable the GPIO port/pin associated with co- as a GPIO input.
- Configure the internal voltage reference to 1.65 V by writing the ACREFCTL register with the value 0x0000.030C.
- 4. Configure comparator 0 to use the internal voltage reference and to *not* invert the output on the C0o pin by writing the **ACCTL0** register with the value of 0x0000.040C.
- Delay for some time.
- 6. Read the comparator output value by reading the **ACSTAT0** register's OVAL value.

Change the level of the signal input on ${\tt CO-}$ to see the ${\tt OVAL}$ value change.

16.4 Register Map

Table 16-4 on page 427 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000.

Table 16-4. Analog Comparators Register Map

16.5 Register Descriptions

The remainder of this section lists and describes the Analog Comparator registers, in numerical order by address offset.

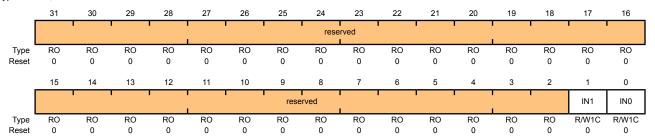

Register 1: Analog Comparator Masked Interrupt Status (ACMIS), offset 0x00

This register provides a summary of the interrupt status (masked) of the comparators.

Analog Comparator Masked Interrupt Status (ACMIS)

Base 0x4003.C000

Offset 0x00 Type R/W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	IN1	R/W1C	0	Comparator 1 Masked Interrupt Status
				Gives the masked interrupt state of this interrupt. Write 1 to this bit to clear the pending interrupt.
0	IN0	R/W1C	0	Comparator 0 Masked Interrupt Status

Gives the masked interrupt state of this interrupt. Write 1 to this bit to clear the pending interrupt.

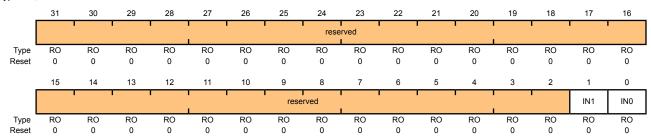

Register 2: Analog Comparator Raw Interrupt Status (ACRIS), offset 0x04

This register provides a summary of the interrupt status (raw) of the comparators.

Analog Comparator Raw Interrupt Status (ACRIS)

Base 0x4003.C000

Offset 0x04
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	IN1	RO	0	Comparator 1 Interrupt Status
				When set, indicates that an interrupt has been generated by comparator 1.
0	IN0	RO	0	Comparator 0 Interrupt Status

When set, indicates that an interrupt has been generated by comparator 0.

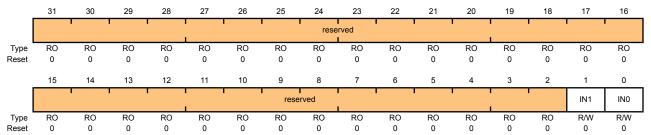

Register 3: Analog Comparator Interrupt Enable (ACINTEN), offset 0x08

This register provides the interrupt enable for the comparators.

Analog Comparator Interrupt Enable (ACINTEN)

Base 0x4003.C000

Offset 0x08
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	IN1	R/W	0	Comparator 1 Interrupt Enable When set, enables the controller interrupt from the comparator 1 output.
0	IN0	R/W	0	Comparator 0 Interrupt Enable

When set, enables the controller interrupt from the comparator 0 output.

4	ISLVAL	R/W	0	Interrupt Sense Level Value
•	1027/12	1011	Ü	The ISLVAL bit specifies the sense value of the input that generates
				an interrupt if in Level Sense mode. If 0, an interrupt is generated if the comparator output is Low. Otherwise, an interrupt is generated if the comparator output is High.
3:2	ISEN	R/W	0x0	Interrupt Sense
				The ISEN field specifies the sense of the comparator output that generates an interrupt. The sense conditioning is as follows:
				Value Function
				0x0 Level sense, see ISLVAL
				0x1 Falling edge
				0x2 Rising edge
				0x3 Either edge
1	CINV	R/W	0	Comparator Output Invert
				The CINV bit conditionally inverts the output of the comparator. If 0, the output of the comparator is unchanged. If 1, the output of the comparator is inverted prior to being processed by hardware.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

17 Pulse Width Modulator (PWM)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

The Stellaris[®] PWM module consists of one PWM generator block and a control block. The PWM generator block contains one timer (16-bit down or up/down counter), two PWM comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

The PWM generator block produces two PWM signals that can either be independent signals (other than being based on the same timer and therefore having the same frequency) or a single pair of complementary signals with dead-band delays inserted. The output of the PWM generation block is managed by the output control block before being passed to the device pins.

The Stellaris[®] PWM module provides a great deal of flexibility. It can generate simple PWM signals, such as those required by a simple charge pump. It can also generate paired PWM signals with dead-band delays, such as those required by a half-H bridge driver.

17.1 Block Diagram

Figure 17-1 on page 435 provides a block diagram of a Stellaris[®] PWM module. The LM3S2432 controller contains one generator block (PWM0) and generates two independent PWM signals or one paired PWM signal with dead-band delays inserted.

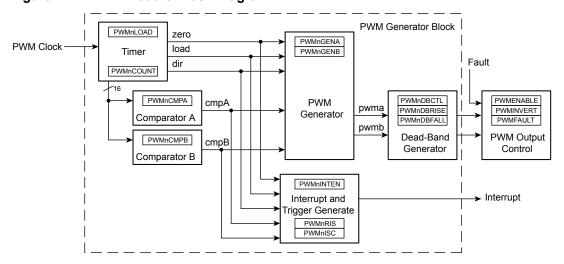

Figure 17-1. PWM Module Block Diagram

17.2 Functional Description

17.2.1 **PWM Timer**

The timer runs in one of two modes: Count-Down mode or Count-Up/Down mode. In Count-Down mode, the timer counts from the load value to zero, goes back to the load value, and continues counting down. In Count-Up/Down mode, the timer counts from zero up to the load value, back down to zero, back up to the load value, and so on. Generally, Count-Down mode is used for

generating left- or right-aligned PWM signals, while the Count-Up/Down mode is used for generating center-aligned PWM signals.

The timers output three signals that are used in the PWM generation process: the direction signal (this is always Low in Count-Down mode, but alternates between Low and High in Count-Up/Down mode), a single-clock-cycle-width High pulse when the counter is zero, and a single-clock-cycle-width High pulse when the counter is equal to the load value. Note that in Count-Down mode, the zero pulse is immediately followed by the load pulse.

17.2.2 PWM Comparators

There are two comparators in the PWM generator that monitor the value of the counter; when either match the counter, they output a single-clock-cycle-width High pulse. When in Count-Up/Down mode, these comparators match both when counting up and when counting down; they are therefore qualified by the counter direction signal. These qualified pulses are used in the PWM generation process. If either comparator match value is greater than the counter load value, then that comparator never outputs a High pulse.

Figure 17-2 on page 436 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Down mode. Figure 17-3 on page 437 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Up/Down mode.

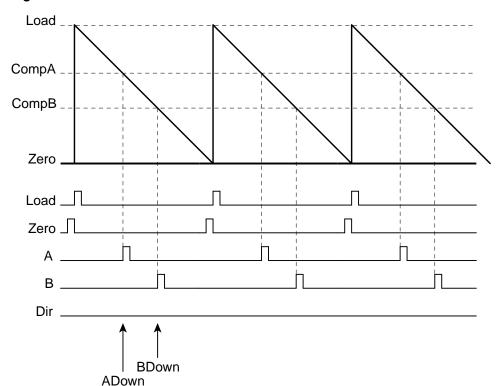

Figure 17-2. PWM Count-Down Mode

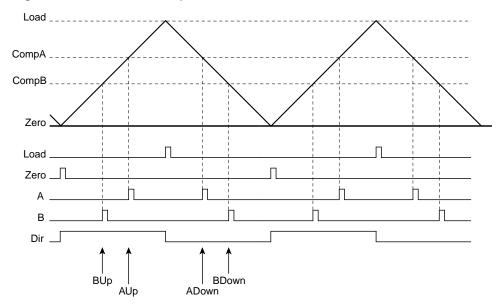

Figure 17-3. PWM Count-Up/Down Mode

17.2.3 PWM Signal Generator

The PWM generator takes these pulses (qualified by the direction signal), and generates two PWM signals. In Count-Down mode, there are four events that can affect the PWM signal: zero, load, match A down, and match B down. In Count-Up/Down mode, there are six events that can affect the PWM signal: zero, load, match A down, match A up, match B down, and match B up. The match A or match B events are ignored when they coincide with the zero or load events. If the match A and match B events coincide, the first signal, PWMA, is generated based only on the match A event, and the second signal, PWMB, is generated based only on the match B event.

For each event, the effect on each output PWM signal is programmable: it can be left alone (ignoring the event), it can be toggled, it can be driven Low, or it can be driven High. These actions can be used to generate a pair of PWM signals of various positions and duty cycles, which do or do not overlap. Figure 17-4 on page 437 shows the use of Count-Up/Down mode to generate a pair of center-aligned, overlapped PWM signals that have different duty cycles.

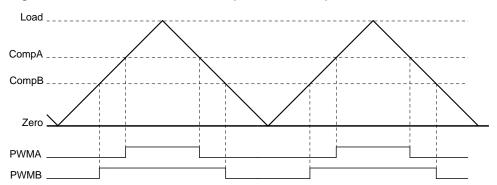

Figure 17-4. PWM Generation Example In Count-Up/Down Mode

In this example, the first generator is set to drive High on match A up, drive Low on match A down, and ignore the other four events. The second generator is set to drive High on match B up, drive Low on match B down, and ignore the other four events. Changing the value of comparator A

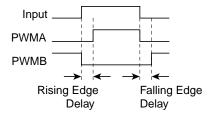

changes the duty cycle of the PWMA signal, and changing the value of comparator B changes the duty cycle of the PWMB signal.

17.2.4 Dead-Band Generator

The two PWM signals produced by the PWM generator are passed to the dead-band generator. If disabled, the PWM signals simply pass through unmodified. If enabled, the second PWM signal is lost and two PWM signals are generated based on the first PWM signal. The first output PWM signal is the input signal with the rising edge delayed by a programmable amount. The second output PWM signal is the inversion of the input signal with a programmable delay added between the falling edge of the input signal and the rising edge of this new signal.

This is therefore a pair of active High signals where one is always High, except for a programmable amount of time at transitions where both are Low. These signals are therefore suitable for driving a half-H bridge, with the dead-band delays preventing shoot-through current from damaging the power electronics. Figure 17-5 on page 438 shows the effect of the dead-band generator on an input PWM signal.

Figure 17-5. PWM Dead-Band Generator

17.2.5 Interrupt/ADC-Trigger Selector

The PWM generator also takes the same four (or six) counter events and uses them to generate an interrupt or an ADC trigger. Any of these events or a set of these events can be selected as a source for an interrupt; when any of the selected events occur, an interrupt is generated. Additionally, the same event, a different event, the same set of events, or a different set of events can be selected as a source for an ADC trigger; when any of these selected events occur, an ADC trigger pulse is generated. The selection of events allows the interrupt or ADC trigger to occur at a specific position within the PWM signal. Note that interrupts and ADC triggers are based on the raw events; delays in the PWM signal edges caused by the dead-band generator are not taken into account.

17.2.6 Synchronization Methods

There is a global reset capability that can reset the counter of the PWM generator.

The counter load values and comparator match values of the PWM generator can be updated in two ways. The first is immediate update mode, where a new value is used as soon as the counter reaches zero. By waiting for the counter to reach zero, a guaranteed behavior is defined, and overly short or overly long output PWM pulses are prevented.

The other update method is synchronous, where the new value is not used until a global synchronized update signal is asserted, at which point the new value is used as soon as the counter reaches zero. This second mode allows multiple items to be updated simultaneously without odd effects during the update; everything runs from the old values until a point at which they all run from the new values.

17.2.7 Fault Conditions

There are two external conditions that affect the PWM block; the signal input on the Fault pin and the stalling of the controller by a debugger. There are two mechanisms available to handle such conditions: the output signals can be forced into an inactive state and/or the PWM timers can be stopped.

Each output signal has a fault bit. If set, a fault input signal causes the corresponding output signal to go into the inactive state. If the inactive state is a safe condition for the signal to be in for an extended period of time, this keeps the output signal from driving the outside world in a dangerous manner during the fault condition. A fault condition can also generate a controller interrupt.

Each PWM generator can also be configured to stop counting during a stall condition. The user can select for the counters to run until they reach zero then stop, or to continue counting and reloading. A stall condition does not generate a controller interrupt.

17.2.8 Output Control Block

With the PWM generator block producing two raw PWM signals, the output control block takes care of the final conditioning of the PWM signals before they go to the pins. Via a single register, the set of PWM signals that are actually enabled to the pins can be modified; this can be used, for example, to perform commutation of a brushless DC motor with a single register write (and without modifying the individual PWM generators, which are modified by the feedback control loop). Similarly, fault control can disable any of the PWM signals as well. A final inversion can be applied to any of the PWM signals, making them active Low instead of the default active High.

17.3 Initialization and Configuration

The following example shows how to initialize the PWM Generator 0 with a 25-KHz frequency, and with a 25% duty cycle on the PWM0 pin and a 75% duty cycle on the PWM1 pin. This example assumes the system clock is 20 MHz.

- 1. Enable the PWM clock by writing a value of 0x0010.0000 to the **RCGC0** register in the System Control module.
- Enable the clock to the appropriate GPIO module via the RCGC2 register in the System Control module.
- 3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register.
- 4. Configure the Run-Mode Clock Configuration (RCC) register in the System Control module to use the PWM divide (USEPWMDIV) and set the divider (PWMDIV) to divide by 2 (000).
- 5. Configure the PWM generator for countdown mode with immediate updates to the parameters.
 - Write the **PWM0CTL** register with a value of 0x0000.0000.
 - Write the PWM0GENA register with a value of 0x0000.008C.
 - Write the PWM0GENB register with a value of 0x0000.080C.
- 6. Set the period. For a 25-KHz frequency, the period = 1/25,000, or 40 microseconds. The PWM clock source is 10 MHz; the system clock divided by 2. This translates to 400 clock ticks per period. Use this value to set the PWM0LOAD register. In Count-Down mode, set the Load field in the PWM0LOAD register to the requested period minus one.

- Write the PWM0LOAD register with a value of 0x0000.018F.
- 7. Set the pulse width of the PWM0 pin for a 25% duty cycle.
 - Write the **PWM0CMPA** register with a value of 0x0000.012B.
- 8. Set the pulse width of the PWM1 pin for a 75% duty cycle.
 - Write the **PWM0CMPB** register with a value of 0x0000.0063.
- 9. Start the timers in PWM generator 0.
 - Write the **PWM0CTL** register with a value of 0x0000.0001.
- 10. Enable PWM outputs.
 - Write the **PWMENABLE** register with a value of 0x0000.0003.

17.4 Register Map

Table 17-1 on page 440 lists the PWM registers. The offset listed is a hexadecimal increment to the register's address, relative to the PWM base address of 0x4002.8000.

Table 17-1. PWM Register Map

Offset	Name	Type	Reset	Description	See page

17.5 Register Descriptions

The remainder of this section lists and describes the PWM registers, in numerical order by address offset.

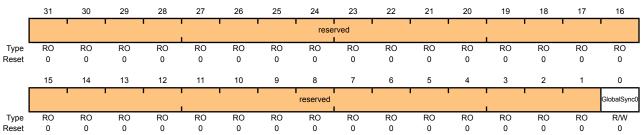

Register 1: PWM Master Control (PWMCTL), offset 0x000

This register provides master control over the PWM generation block.

PWM Master Control (PWMCTL)

Base 0x4002.8000 Offset 0x000

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	GlobalSync0	R/W	0	Update PWM Generator 0

GlobalSync0 R/W 0 Update PWM Generator 0

> Setting this bit causes any queued update to a load or comparator register in PWM generator 0 to be applied the next time the corresponding counter becomes zero. This bit automatically clears when the updates have completed; it cannot be cleared by software.

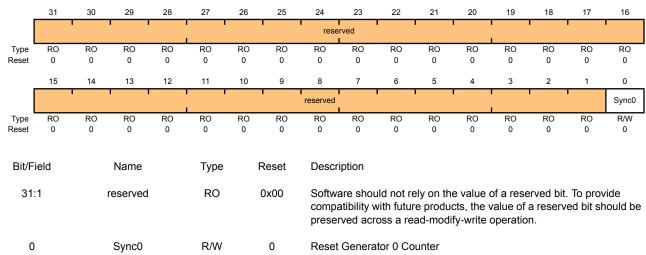

Register 2: PWM Time Base Sync (PWMSYNC), offset 0x004

This register provides a method to perform synchronization of the counters in the PWM generation blocks. Writing a bit in this register to 1 causes the specified counter to reset back to 0; writing multiple bits resets multiple counters simultaneously. The bits auto-clear after the reset has occurred; reading them back as zero indicates that the synchronization has completed.

PWM Time Base Sync (PWMSYNC)

Base 0x4002.8000

Offset 0x004 Type R/W, reset 0x0000.0000

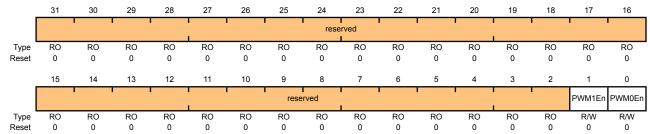

Register 3: PWM Output Enable (PWMENABLE), offset 0x008

This register provides a master control of which generated PWM signals are output to device pins. By disabling a PWM output, the generation process can continue (for example, when the time bases are synchronized) without driving PWM signals to the pins. When bits in this register are set, the corresponding PWM signal is passed through to the output stage, which is controlled by the **PWMINVERT** register. When bits are not set, the PWM signal is replaced by a zero value which is also passed to the output stage.

PWM Output Enable (PWMENABLE)

Base 0x4002.8000 Offset 0x008

Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	PWM1En	R/W	0	PWM1 Output Enable
				When set, allows the generated PWM1 signal to be passed to the device pin.
0	PWM0En	R/W	0	PWM0 Output Enable

When set, allows the generated PWM0 signal to be passed to the device pin.

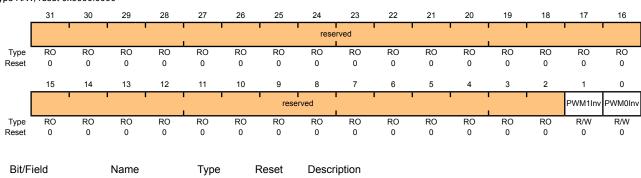

Register 4: PWM Output Inversion (PWMINVERT), offset 0x00C

This register provides a master control of the polarity of the PWM signals on the device pins. The PWM signals generated by the PWM generator are active High; they can optionally be made active Low via this register. Disabled PWM channels are also passed through the output inverter (if so configured) so that inactive channels maintain the correct polarity.

PWM Output Inversion (PWMINVERT)

Base 0x4002.8000

Offset 0x00C Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	PWM1Inv	R/W	0	Invert PWM1 Signal
				When set, the generated PWM1 signal is inverted.
0	PWM0Inv	R/W	0	Invert PWM0 Signal

When set, the generated PWM0 signal is inverted.

Register 5: PWM Output Fault (PWMFAULT), offset 0x010

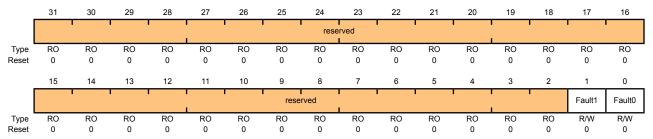

This register controls the behavior of the PWM outputs in the presence of fault conditions. Both the fault input and debug events are considered fault conditions. On a fault condition, each PWM signal can either be passed through unmodified or driven Low. For outputs that are configured for pass-through, the debug event handling on the corresponding PWM generator also determines if the PWM signal continues to be generated.

Fault condition control happens before the output inverter, so PWM signals driven Low on fault are inverted if the channel is configured for inversion (therefore, the pin is driven High on a fault condition).

PWM Output Fault (PWMFAULT)

Base 0x4002.8000

Offset 0x010 Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	Fault1	R/W	0	PWM1 Driven Low on Fault When set, the PWM1 output signal is driven Low on a fault condition.
0	Fault0	R/W	0	PWM0 Driven Low on Fault

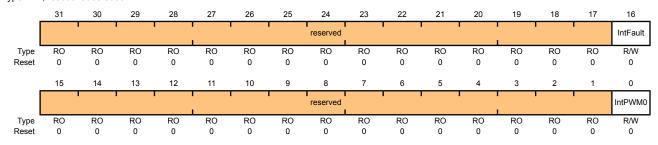

When set, the PWM0 output signal is driven Low on a fault condition.

Register 6: PWM Interrupt Enable (PWMINTEN), offset 0x014

This register controls the global interrupt generation capabilities of the PWM module. The events that can cause an interrupt are the fault input and the individual interrupts from the PWM generator.

PWM Interrupt Enable (PWMINTEN)

Base 0x4002.8000 Offset 0x014 Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:17	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	IntFault	R/W	0	Fault Interrupt Enable When 1, an interrupt occurs when the fault input is asserted.
15:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	IntPWM0	R/W	0	PWM0 Interrupt Enable

When 1, an interrupt occurs when the PWM generator 0 block asserts an interrupt.

Register 7: PWM Raw Interrupt Status (PWMRIS), offset 0x018

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller. The fault interrupt is latched on detection; it must be cleared through the **PWM Interrupt Status and Clear (PWMISC)** register (see page 449). The PWM generator interrupts simply reflect the status of the PWM generator; they are cleared via the interrupt status register in the PWM generator block. Bits set to 1 indicate the events that are active; a zero bit indicates that the event in question is not active.

PWM Raw Interrupt Status (PWMRIS)

Base 0x4002.8000 Offset 0x018

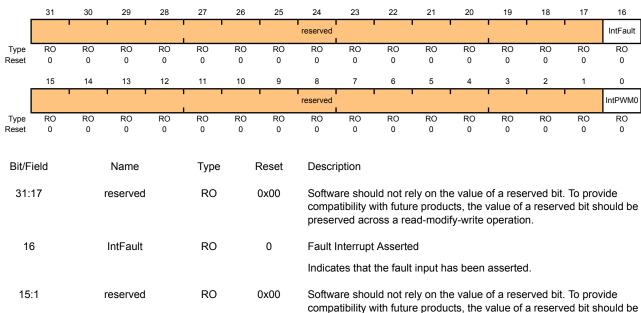

0

IntPWM0

RO

0

Type RO, reset 0x0000.0000

Indicates that the PWM generator 0 block is asserting its interrupt.

preserved across a read-modify-write operation.

PWM0 Interrupt Asserted

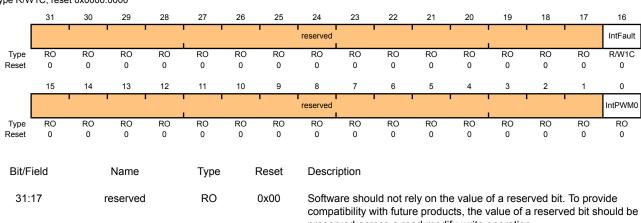

Register 8: PWM Interrupt Status and Clear (PWMISC), offset 0x01C

This register provides a summary of the interrupt status of the PWM generator block. A bit set to 1 indicates that the generator block is asserting an interrupt. The individual interrupt status registers must be consulted to determine the reason for the interrupt, and used to clear the interrupt. For the fault interrupt, a write of 1 to that bit position clears the latched interrupt status.

PWM Interrupt Status and Clear (PWMISC)

Base 0x4002.8000

Offset 0x01C Type R/W1C, reset 0x0000.0000

		• • • • • • • • • • • • • • • • • • • •		·
31:17	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	IntFault	R/W1C	0	Fault Interrupt Asserted Indicates if the fault input is asserting an interrupt.
15:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	IntPWM0	RO	0	PWM0 Interrupt Status

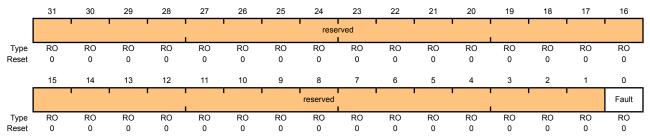

Indicates if the PWM generator 0 block is asserting an interrupt.

Register 9: PWM Status (PWMSTATUS), offset 0x020

This register provides the status of the Fault input signal.

PWM Status (PWMSTATUS)

Base 0x4002.8000 Offset 0x020 Type RO, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	Fault	RO	0	Fault Interrupt Status

When set to 1, indicates the fault input is asserted.

Register 10: PWM0 Control (PWM0CTL), offset 0x040

This register configures the PWM signal generation block. The Register Update mode, Debug mode, Counting mode, and Block Enable mode are all controlled via this register. The block produces the PWM signals, which can be either two independent PWM signals (from the same counter), or a paired set of PWM signals with dead-band delays added.

These registers configure the PWM signal generation blocks (PWM0CTL controls the PWM generator 0 block, and so on). The Register Update mode, Debug mode, Counting mode, and Block Enable mode are all controlled via these registers. The blocks produce the PWM signals, which can be either two independent PWM signals (from the same counter), or a paired set of PWM signals with dead-band delays added.

The PWM0 block produces the PWM0 and PWM1 outputs.

								runnin	The behavior of the counter in Debug mode. If 0, the counter stops running when it next reaches 0, and continues running again when no longer in Debug mode. If 1, the counter always runs.								

Bit/Field	Name	Type	Reset	Description
1	Mode	R/W	0	Counter Mode
				The mode for the counter. If 0, the counter counts down from the load value to 0 and then wraps back to the load value (Count-Down mode). If 1, the counter counts up from 0 to the load value, back down to 0, and then repeats (Count-Up/Down mode).
0	Enable	R/W	0	PWM Block Enable
				Master enable for the PWM generation block. If 0, the entire block is disabled and not clocked. If 1, the block is enabled and produces PWM signals.

Register 11: PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044

This register controls the interrupt and ADC trigger generation capabilities of the PWM generator. The events that can cause an interrupt or an ADC trigger are:

- The counter being equal to the load register
- The counter being equal to zero
- The counter being equal to the comparator A register while counting up
- The counter being equal to the comparator A register while counting down
- The counter being equal to the comparator B register while counting up
- The counter being equal to the comparator B register while counting down

Any combination of these events can generate either an interruptor an ADC trigger, though no determination can be made as to the actual event that caused an ADC trigger if more than one is specified.

0	IntCntZero	R/W	0	Interrupt for Counter=0
				When 1, an interrupt occurs when the counter is 0.

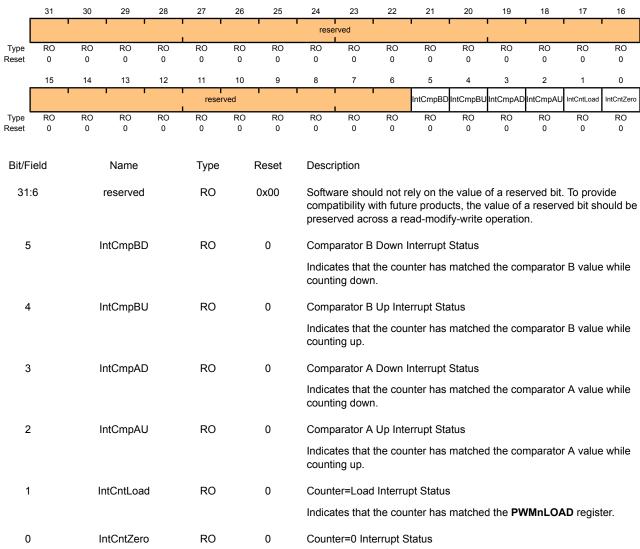

Register 12: PWM0 Raw Interrupt Status (PWM0RIS), offset 0x048

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller. Bits set to 1 indicate the latched events that have occurred; a 0 bit indicates that the event in question has not occurred.

PWM0 Raw Interrupt Status (PWM0RIS)

Base 0x4002.8000 Offset 0x048

Type RO, reset 0x0000.0000

Indicates that the counter has matched 0.

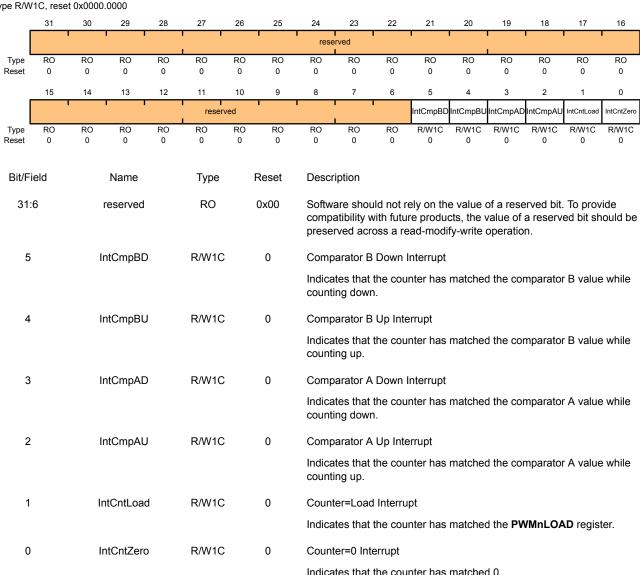

Register 13: PWM0 Interrupt Status and Clear (PWM0ISC), offset 0x04C

This register provides the current set of interrupt sources that are asserted to the controller. Bits set to 1 indicate the latched events that have occurred; a 0 bit indicates that the event in question has not occurred. These are R/W1C registers; writing a 1 to a bit position clears the corresponding interrupt reason.

PWM0 Interrupt Status and Clear (PWM0ISC)

Base 0x4002.8000

Offset 0x04C Type R/W1C, reset 0x0000.0000

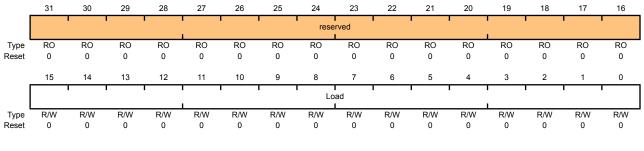

Register 14: PWM0 Load (PWM0LOAD), offset 0x050

This register contains the load value for the PWM counter. Based on the counter mode, either this value is loaded into the counter after it reaches zero, or it is the limit of up-counting after which the counter decrements back to zero. If the Load Value Update mode is immediate, this value is used the next time the counter reaches zero; if the mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 442). If this register is re-written before the actual update occurs, the previous value is never used and is lost.

PWM0 Load (PWM0LOAD)

Base 0x4002.8000 Offset 0x050

Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	Load	R/W	0	Counter Load Value

The counter load value.

Register 15: PWM0 Counter (PWM0COUNT), offset 0x054

This register contains the current value of the PWM counter. When this value matches the load register, a pulse is output; this can drive the generation of a PWM signal (via the **PWMnGENA/PWMnGENB** registers, see page 461 and page 464) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register, see page 453). A pulse with the same capabilities is generated when this value is zero.

PWM0 Counter (PWM0COUNT)

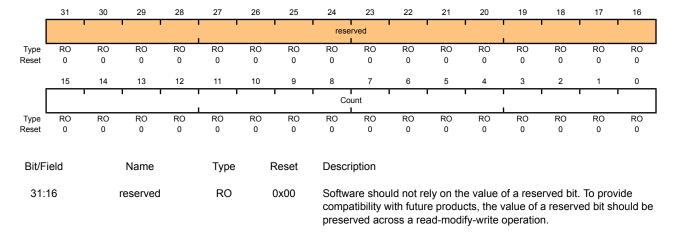

Base 0x4002.8000 Offset 0x054 Type RO, reset 0x0000.0000

15:0

Count

RO

0x00

Counter Value

The current value of the counter.

Register 16: PWM0 Compare A (PWM0CMPA), offset 0x058

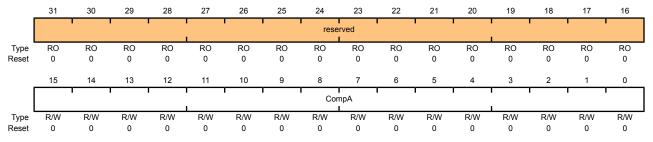

This register contains a value to be compared against the counter. When this value matches the counter, a pulse is output; this can drive the generation of a PWM signal (via the **PWMnGENA/PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register (see page 457), then no pulse is ever output.

If the comparator A update mode is immediate (based on the CmpAUpd bit in the **PWMnCTL** register), then this 16-bit CompA value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 442). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWM0 Compare A (PWM0CMPA)

Base 0x4002.8000 Offset 0x058

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	CompA	R/W	0x00	Comparator A Value

The value to be compared against the counter.

Register 17: PWM0 Compare B (PWM0CMPB), offset 0x05C

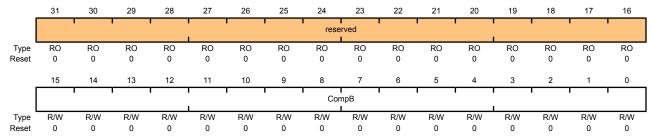

This register contains a value to be compared against the counter. When this value matches the counter, a pulse is output; this can drive the generation of a PWM signal (via the **PWMnGENA/PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register, then no pulse is ever output.

IF the comparator B update mode is immediate (based on the CmpBUpd bit in the **PWMnCTL** register), then this 16-bit CompB value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 442). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWM0 Compare B (PWM0CMPB)

Base 0x4002.8000 Offset 0x05C

Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	CompB	R/W	0x00	Comparator B Value

The value to be compared against the counter.

Register 18: PWM0 Generator A Control (PWM0GENA), offset 0x060

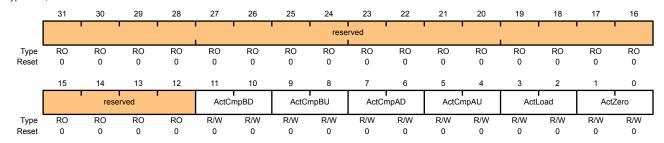

This register controls the generation of the PWMnA signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators. When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the PWM signal that is produced.

The **PWM0GENA** register controls generation of the PWM0A signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare A action is taken and the compare B action is ignored.

PWM0 Generator A Control (PWM0GENA)

Base 0x4002.8000 Offset 0x060 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:10	ActCmpBD	R/W	0x0	Action for Comparator B Down

The action to be taken when the counter matches comparator B while counting down.

The table below defines the effect of the event on the output signal.

Value Description

0x0 Do nothing.

0x1 Invert the output signal.

0x2 Set the output signal to 0.

0x3 Set the output signal to 1.

Bit/Field	Name	Туре	Reset	Description
9:8	ActCmpBU	R/W	0x0	Action for Comparator B Up
				The action to be taken when the counter matches comparator B while counting up. Occurs only when the Mode bit in the PWMnCTL register (see page 451) is set to 1.
				The table below defines the effect of the event on the output signal.
				Value Description
				0x0 Do nothing.
				0x1 Invert the output signal.
				0x2 Set the output signal to 0.
				0x3 Set the output signal to 1.
7:6	ActCmpAD	R/W	0x0	Action for Comparator A Down
				The action to be taken when the counter matches comparator A while counting down.
				The table below defines the effect of the event on the output signal.
				Value Description
				0x0 Do nothing.
				0x1 Invert the output signal.
				0x2 Set the output signal to 0.
				0x3 Set the output signal to 1.
5:4	ActCmpAU	R/W	0x0	Action for Comparator A Up
				The action to be taken when the counter matches comparator A while counting up. Occurs only when the Mode bit in the PWMnCTL register is set to 1.
				The table below defines the effect of the event on the output signal.
				Value Description
				0x0 Do nothing.
				0x1 Invert the output signal.
				0x2 Set the output signal to 0.
				0x3 Set the output signal to 1.
3:2	ActLoad	R/W	0x0	Action for Counter=Load
				The action to be taken when the counter matches the load value.
				The table below defines the effect of the event on the output signal.
				Value Description
				0x0 Do nothing.
				0x1 Invert the output signal.
				0x2 Set the output signal to 0.
				0x3 Set the output signal to 1.

Bit/Field	Name	Туре	Reset	Description
1:0	ActZero	R/W	0x0	Action for Counter=0
				The action to be taken when the counter is zero.
				The table below defines the effect of the event on the output signal.
				Value Description
				0x0 Do nothing.
				0x1 Invert the output signal.
				0x2 Set the output signal to 0.
				0x3 Set the output signal to 1.

Register 19: PWM0 Generator B Control (PWM0GENB), offset 0x064

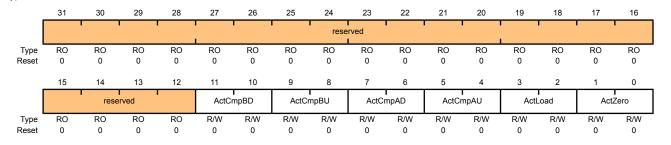

This register controls the generation of the PWMnB signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators. When the counter is running in Down mode, only four of these events occur; when running in Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the PWM signal that is produced.

The **PWM0GENB** register controls generation of the PWM0B signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare B action is taken and the compare A action is ignored.

				The action to be taken when the counter is 0.
				The table below defines the effect of the event on the output signal.
				Value Description
				0x0 Do nothing.
				0x1 Invert the output signal.
				0x2 Set the output signal to 0.
				0x3 Set the output signal to 1.

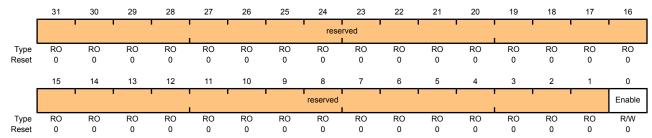

Register 20: PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068

The **PWM0DBCTL** register controls the dead-band generator, which produces the PWM0 and PWM1 signals based on the PWM0A and PWM0B signals. When disabled, the PWM0A signal passes through to the PWM0 signal and the PWM0B signal passes through to the PWM1 signal. When enabled and inverting the resulting waveform, the PWM0B signal is ignored; the PWM0 signal is generated by delaying the rising edge(s) of the PWM0A signal by the value in the **PWM0DBRISE** register (see page 468), and the PWM1 signal is generated by delaying the falling edge(s) of the PWM0A signal by the value in the **PWM0DBFALL** register (see page 469).

PWM0 Dead-Band Control (PWM0DBCTL)

Base 0x4002.8000 Offset 0x068

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	Enable	R/W	0	Dead-Band Generator Enable

When set, the dead-band generator inserts dead bands into the output signals; when clear, it simply passes the PWM signals through.

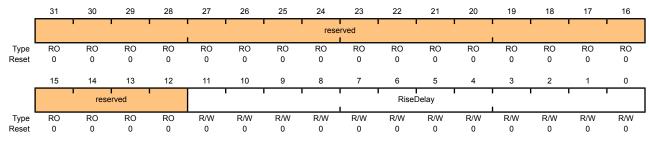

Register 21: PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C

The **PWM0DBRISE** register contains the number of clock ticks to delay the rising edge of the PWM0A signal when generating the PWM0 signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, the **PWM0DBRISE** register is ignored. If the value of this register is larger than the width of a High pulse on the input PWM signal, the rising-edge delay consumes the entire High time of the signal, resulting in no High time on the output. Care must be taken to ensure that the input High time always exceeds the rising-edge delay.

PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE)

Base 0x4002.8000 Offset 0x06C

Type R/W, reset 0x0000.0000

Bit/Field	Name	Туре	Reset	Description
31:12	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:0	RiseDelay	R/W	0	Dead-Band Rise Delay

The number of clock ticks to delay the rising edge.

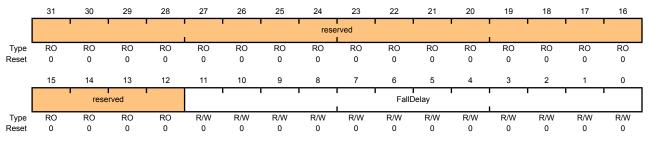

Register 22: PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL), offset 0x070

The **PWM0DBFALL** register contains the number of clock ticks to delay the falling edge of the PWM0A signal when generating the PWM1 signal. If the dead-band generator is disabled, this register is ignored. If the value of this register is larger than the width of a Low pulse on the input PWM signal, the falling-edge delay consumes the entire Low time of the signal, resulting in no Low time on the output. Care must be taken to ensure that the input Low time always exceeds the falling-edge delay.

PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL)

Base 0x4002.8000 Offset 0x070

Type R/W, reset 0x0000.0000

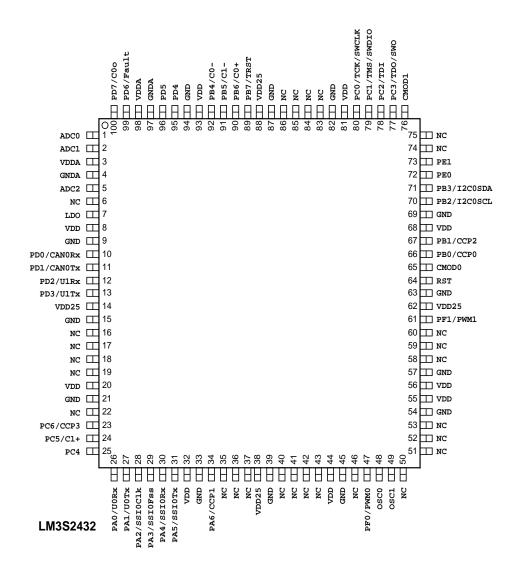

Bit/Field	Name	Туре	Reset	Description
31:12	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:0	FallDelay	R/W	0x00	Dead-Band Fall Delay

The number of clock ticks to delay the falling edge.

18 Pin Diagram

Figure 18-1 on page 470 shows the pin diagram and pin-to-signal-name mapping.

Figure 18-1. Pin Connection Diagram

19 Signal Tables

The following tables list the signals available for each pin. Functionality is enabled by software with the **GPIOAFSEL** register.

Important: All multiplexed pins are GPIOs by default, with the exception of the five JTAG pins (PB7 and PC[3:0]) which default to the JTAG functionality.

Table 19-1 on page 471 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Table 19-2 on page 475 lists the signals in alphabetical order by signal name.

Table 19-3 on page 479 groups the signals by functionality, except for GPIOs. Table 19-4 on page 481 lists the GPIO pins and their alternate functionality.

Table 19-1. Signals by Pin Number

Pin Number	Pin Name	Pin Type	Buffer Type	Description
1	ADC0	I	Analog	Analog-to-digital converter input 0.
2	ADC1	I	Analog	Analog-to-digital converter input 1.
3	VDDA	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.
4	GNDA	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
5	ADC2	I	Analog	Analog-to-digital converter input 2.
6	NC	-	-	No connect
7	LDO	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 μF or greater. When the on-chip LDO is used to provide power to the logic, the LDO pin must also be connected to the VDD25 pins at the board level in addition to the decoupling capacitor(s).
8	VDD	-	Power	Positive supply for I/O and some logic.
9	GND	-	Power	Ground reference for logic and I/O pins.
10	PD0	I/O	TTL	GPIO port D bit 0
	CAN0Rx	I	TTL	CAN module 0 receive
11	PD1	I/O	TTL	GPIO port D bit 1
	CAN0Tx	0	TTL	CAN module 0 transmit
12	PD2	I/O	TTL	GPIO port D bit 2
	U1Rx	I	TTL	UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.
13	PD3	I/O	TTL	GPIO port D bit 3
	UlTx	0	TTL	UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.

Pin Number	Pin Name	Pin Type	Buffer Type	Description

	SWCLK	I	TTL	JTAG/SWD CLK
81	VDD	-	Power	Positive supply for I/O and some logic.
82	GND	-	Power	Ground reference for logic and I/O pins.
83	NC	-	-	No connect
84	NC	-	-	No connect
85	NC	-	-	No connect
86	NC	-	-	No connect
87	GND	-	Power	Ground reference for logic and I/O pins.
88	VDD25	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
89	PB7	I/O	TTL	GPIO port B bit 7
	TRST	I	TTL	JTAG TRSTn
90	РВ6	I/O	TTL	GPIO port B bit 6
	C0+	I	Analog	Analog comparator 0 positive input
91	PB5	I/O	TTL	GPIO port B bit 5
	C1-	I	Analog	Analog comparator 1 negative input
92	PB4	I/O	TTL	GPIO port B bit 4
	C0-	I	Analog	Analog comparator 0 negative input
93	VDD	-	Power	Positive supply for I/O and some logic.
94	GND	-	Power	Ground reference for logic and I/O pins.
95	PD4	I/O	TTL	GPIO port D bit 4
96	PD5	I/O	TTL	GPIO port D bit 5
97	GNDA	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
98	VDDA	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.

Pin Number	Pin Name	Pin Type	Buffer Type	Description
99	PD6	I/O	TTL	GPIO port D bit 6
	Fault	I	TTL	PWM Fault
100	PD7	I/O	TTL	GPIO port D bit 7
	C0o	0	TTL	Analog comparator 0 output

Table 19-2. Signals by Signal Name

Pin Name	Pin Number	Pin Type	Buffer Type	Description
ADC0	1	I	Analog	Analog-to-digital converter input 0.
ADC1	2	ļ	Analog	Analog-to-digital converter input 1.
ADC2	5	ļ	Analog	Analog-to-digital converter input 2.
C0+	90	I	Analog	Analog comparator 0 positive input
C0-	92	I	Analog	Analog comparator 0 negative input
C0o	100	0	TTL	Analog comparator 0 output
C1+	24	I	Analog	Analog comparator positive input
C1-	91	I	Analog	Analog comparator 1 negative input
CAN0Rx	10	I	TTL	CAN module 0 receive
CAN0Tx	11	0	TTL	CAN module 0 transmit
CCP0	66	I/O	TTL	Capture/Compare/PWM 0
CCP1	34	I/O	TTL	Capture/Compare/PWM 1
CCP2	67	I/O	TTL	Capture/Compare/PWM 2
CCP3	23	I/O	TTL	Capture/Compare/PWM 3
CMOD0	65	I/O	TTL	CPU Mode bit 0. Input must be set to logic 0 (grounded); other encodings reserved.
CMOD1	76	I/O	TTL	CPU Mode bit 1. Input must be set to logic 0 (grounded); other encodings reserved.
Fault	99	ļ	TTL	PWM Fault
GND	9	-	Power	Ground reference for logic and I/O pins.
GND	15	-	Power	Ground reference for logic and I/O pins.
GND	21	-	Power	Ground reference for logic and I/O pins.
GND	33	-	Power	Ground reference for logic and I/O pins.
GND	39	-	Power	Ground reference for logic and I/O pins.
GND	45	-	Power	Ground reference for logic and I/O pins.
GND	54	-	Power	Ground reference for logic and I/O pins.
GND	57	-	Power	Ground reference for logic and I/O pins.
GND	63	-	Power	Ground reference for logic and I/O pins.
GND	69	-	Power	Ground reference for logic and I/O pins.
GND	82	-	Power	Ground reference for logic and I/O pins.
GND	87	-	Power	Ground reference for logic and I/O pins.
GND	94	-	Power	Ground reference for logic and I/O pins.
GNDA	4	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.

Pin Name	Pin Number	Pin Type	Buffer Type	Description
GNDA	97	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
I2C0SCL	70	I/O	OD	I2C module 0 clock
I2C0SDA	71	I/O	OD	I2C module 0 data
LDO	7	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 µF or greater. When the on-chip LDO is used to provide power to the logic, the LDO pin must also be connected to the VDD25 pins at the board level in addition to the decoupling capacitor(s).

PE1	73	I/O	TTL	GPIO port E bit 1
PF0	47	I/O	TTL	GPIO port F bit 0
PF1	61	I/O	TTL	GPIO port F bit 1
PWM0	47	0	TTL	PWM 0
PWM1	61	0	TTL	PWM 1
RST	64	I	TTL	System reset input.
SSIOClk	28	I/O	TTL	SSI module 0 clock
SSI0Fss	29	I/O	TTL	SSI module 0 frame
SSIORx	30	ı	TTL	SSI module 0 receive
SSIOTx	31	0	TTL	SSI module 0 transmit
SWCLK	80	I	TTL	JTAG/SWD CLK
SWDIO	79	I/O	TTL	JTAG TMS and SWDIO
SWO	77	0	TTL	JTAG TDO and SWO

Pin Name	Pin Number	Pin Type	Buffer Type	Description
TCK	80	I	TTL	JTAG/SWD CLK
TDI	78	I	TTL	JTAG TDI
TDO	77	0	TTL	JTAG TDO and SWO
TMS	79	I/O	TTL	JTAG TMS and SWDIO
TRST	89	I	TTL	JTAG TRSTn
U0Rx	26	I	TTL	UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.
UOTx	27	0	TTL	UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.
U1Rx	12	I	TTL	UART module 1 receive. When in IrDA mode, this signal has IrDA modulation.
UlTx	13	0	TTL	UART module 1 transmit. When in IrDA mode, this signal has IrDA modulation.
VDD	8	-	Power	Positive supply for I/O and some logic.
VDD	20	-	Power	Positive supply for I/O and some logic.
VDD	32	-	Power	Positive supply for I/O and some logic.
VDD	44	-	Power	Positive supply for I/O and some logic.
VDD	55	-	Power	Positive supply for I/O and some logic.
VDD	56	-	Power	Positive supply for I/O and some logic.
VDD	68	-	Power	Positive supply for I/O and some logic.
VDD	81	-	Power	Positive supply for I/O and some logic.
VDD	93	-	Power	Positive supply for I/O and some logic.
VDD25	14	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
VDD25	38	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
VDD25	62	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
VDD25	88	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
VDDA	3	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.
VDDA	98	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.

Table 19-3. Signals by Function, Except for GPIO

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
ADC	ADC0	1	I	Analog	Analog-to-digital converter input 0.
	ADC1	2	I	Analog	Analog-to-digital converter input 1.
	ADC2	5	I	Analog	Analog-to-digital converter input 2.
Analog	C0+	90	I	Analog	Analog comparator 0 positive input
Comparators	C0-	92	I	Analog	Analog comparator 0 negative input
	C0o	100	0	TTL	Analog comparator 0 output
	C1+	24	ļ	Analog	Analog comparator positive input
	C1-	91	ļ	Analog	Analog comparator 1 negative input
Controller Area	CAN0Rx	10	Į	TTL	CAN module 0 receive
Network	CAN0Tx	11	0	TTL	CAN module 0 transmit

Timers	CCP1	34	I/O	TTL	Capture/Compare/PWM 1
	CCP2	67	I/O	TTL	Capture/Compare/PWM 2
	CCP3	23	I/O	TTL	Capture/Compare/PWM 3
I2C	I2C0SCL	70	I/O	OD	I2C module 0 clock
	I2C0SDA	71	I/O	OD	I2C module 0 data
JTAG/SWD/SWO	SWCLK	80	I	TTL	JTAG/SWD CLK
	SWDIO	79	I/O	TTL	JTAG TMS and SWDIO
	SWO	77	0	TTL	JTAG TDO and SWO
	TCK	80	I	TTL	JTAG/SWD CLK
	TDI	78	I	TTL	JTAG TDI
	TDO	77	0	TTL	JTAG TDO and SWO
	TMS	79	I/O	TTL	JTAG TMS and SWDIO
PWM	Fault	99	I	TTL	PWM Fault
	PWM0	47	0	TTL	PWM 0
	PWM1	61	0	TTL	PWM 1

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
Power	GND	9	-	Power	Ground reference for logic and I/O pins.
	GND	15	-	Power	Ground reference for logic and I/O pins.
	GND	21	-	Power	Ground reference for logic and I/O pins.
	GND	33	-	Power	Ground reference for logic and I/O pins.
	GND	39	-	Power	Ground reference for logic and I/O pins.
	GND	45	-	Power	Ground reference for logic and I/O pins.
	GND	54	-	Power	Ground reference for logic and I/O pins.
	GND	57	-	Power	Ground reference for logic and I/O pins.
	GND	63	-	Power	Ground reference for logic and I/O pins.
	GND	69	-	Power	Ground reference for logic and I/O pins.
	GND	82	-	Power	Ground reference for logic and I/O pins.
	GND	87	-	Power	Ground reference for logic and I/O pins.
	GND	94	-	Power	Ground reference for logic and I/O pins.
	GNDA	4	-	Power	The ground reference for the analog circuits (ADC Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
	GNDA	97	-	Power	The ground reference for the analog circuits (ADC Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
	LDO	7	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin ar GND of 1 μ F or greater. When the on-chip LDO used to provide power to the logic, the LDO pin must also be connected to the VDD25 pins at the board level in addition to the decoupling capacitor(s).
	VDD	8	-	Power	Positive supply for I/O and some logic.
	VDD	20	-	Power	Positive supply for I/O and some logic.
	VDD	32	-	Power	Positive supply for I/O and some logic.
	VDD	44	-	Power	Positive supply for I/O and some logic.
	VDD	55	-	Power	Positive supply for I/O and some logic.
	VDD	56	-	Power	Positive supply for I/O and some logic.
	VDD	68	-	Power	Positive supply for I/O and some logic.
	VDD	81	-	Power	Positive supply for I/O and some logic.
	VDD	93	-	Power	Positive supply for I/O and some logic.
	VDD25	14	-	Power	Positive supply for most of the logic function, including the processor core and most peripheral
	VDD25	38	-	Power	Positive supply for most of the logic function, including the processor core and most peripheral
	VDD25	62	-	Power	Positive supply for most of the logic function, including the processor core and most peripheral
	VDD25	88	-	Power	Positive supply for most of the logic function, including the processor core and most peripheral
	VDDA	3	-	Power	

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
					The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.
	VDDA	98	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.
SSI	SSI0Clk	28	I/O	TTL	SSI module 0 clock
	SSI0Fss	29	I/O	TTL	SSI module 0 frame
	SSI0Rx	30	I	TTL	SSI module 0 receive

20 Operating Characteristics

Table 20-1. Temperature Characteristics

Characteristic	Symbol	Value	Unit
Operating temperature range ^a	T _A	-40 to +85	°C

a. Maximum storage temperature is 150°C.

Table 20-2. Thermal Characteristics

Characteristic	Symbol	Value	Unit
Thermal resistance (junction to ambient) ^a	Θ_{JA}	55.3	°C/W
Average junction temperature ^b	T _J	$T_A + (P_{AVG} \cdot \Theta_{JA})$	°C

- a. Junction to ambient thermal resistance θ_{JA} numbers are determined by a package simulator.
- b. Power dissipation is a function of temperature.

21 Electrical Characteristics

21.1 DC Characteristics

21.1.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device.

Note: The device is not guaranteed to operate properly at the maximum ratings.

Table 21-1. Maximum Ratings

Characteristic	Symbol	Value		Unit
۵		Min	Max	
I/O supply voltage (V _{DD})	V _{DD}	0	4	٧
Core supply voltage (V _{DD25})	V _{DD25}	0	4	٧
Analog supply voltage (V _{DDA})	V_{DDA}	0	4	٧
Input voltage	V _{IN}	-0.3	5.5	٧
Maximum current per output pins	I	-	25	mA

a. Voltages are measured with respect to GND.

Important: This device contains circuitry to protect the inputs against damage due to high-static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (for example, either GND or VDD).

21.1.2 Recommended DC Operating Conditions

Table 21-2. Recommended DC Operating Conditions

Parameter	Parameter Name	Min	Nom	Max	Unit
V _{DD}	I/O supply voltage	3.0	3.3	3.6	V
V _{DD25}	Core supply voltage	2.25	2.5	2.75	V
V_{DDA}	Analog supply voltage	3.0	3.3	3.6	V
V _{IH}	High-level input voltage	2.0	-	5.0	V
V _{IL}	Low-level input voltage	-0.3	-	1.3	V
V _{SIH}	High-level input voltage for Schmitt trigger inputs	0.8 * V _{DD}	-	V_{DD}	V
V _{SIL}	Low-level input voltage for Schmitt trigger inputs	0	-	0.2 * V _{DD}	V
V _{OH}	High-level output voltage	2.4	-	-	V
V _{OL}	Low-level output voltage	-	-	0.4	V
I _{OH}	High-level source current, V _{OH} =2.4 V				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA

Parameter	Parameter Name	Min	Nom	Max	Unit
I _{OL}	Low-level sink current, V _{OL} =0.4 V				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA

21.1.3 On-Chip Low Drop-Out (LDO) Regulator Characteristics

Table 21-3. LDO Regulator Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
V _{LDOOUT}	Programmable internal (logic) power supply output value	2.25	2.5	2.75	V
	Output voltage accuracy	-	2%	-	%
t _{PON}	Power-on time	-	-	100	μs
t _{ON}	Time on	-	-	200	μs
t _{OFF}	Time off	-	-	100	μs
V _{STEP}	Step programming incremental voltage	-	50	-	mV
C _{LDO}	External filter capacitor size for internal power supply	1.0	-	3.0	μF

21.1.4 Power Specifications

The power measurements specified in the tables that follow are run on the core processor using SRAM with the following specifications (except as noted):

- $V_{DD} = 3.3 \text{ V}$
- V_{DD25} = 2.50 V
- $V_{DDA} = 3.3 V$
- Temperature = 25°C
- Clock Source (MOSC) =3.579545 MHz Crystal Oscillator
- Main oscillator (MOSC) = enabled
- Internal oscillator (IOSC) = disabled

Table 21-4. Detailed Power Specifications

Parameter	Parameter Name	Conditions	$V_{\rm DD}, V_{\rm DDA}, V_{\rm DDA}$		2.5	Unit	
			Nom	Max	Nom	Max	
I _{DD_RUN}	Run mode 1 (Flash	V _{DD25} = 2.50 V	3	pending ^a	108	pendinga	mA
	loop)	Code= while(1){} executed in Flash					
		Peripherals = All ON					
		System Clock = 50 MHz (with PLL)					
	Run mode 2 (Flash	V _{DD25} = 2.50 V	0	pending ^a	53	pendinga	mA
	loop)	Code= while(1){} executed in Flash					
		Peripherals = All OFF					
		System Clock = 50 MHz (with PLL)					
	Run mode 1 (SRAM loop)	V _{DD25} = 2.50 V	3	pending ^a	102	pendinga	mA
		Code= while(1){} executed in SRAM					
		Peripherals = All ON					
		System Clock = 50 MHz (with PLL)					
	Run mode 2 (SRAM	V _{DD25} = 2.50 V	0	pending ^a	47	pendinga	mA
	loop)	Code= while(1){} executed in SRAM					
		Peripherals = All OFF					
		System Clock = 50 MHz (with PLL)					
I _{DD_SLEEP}	Sleep mode	V _{DD25} = 2.50 V	0	pending ^a	17	pendinga	mA
		Peripherals = All OFF					
		System Clock = 50 MHz (with PLL)					
I _{DD_DEEPSLEEP}	Deep-Sleep mode	LDO = 2.25 V	0.143	pending ^a	0.18	pendinga	mA
		Peripherals = All OFF					
		System Clock = IOSC30KHZ/64					

a. Pending characterization completion.

21.1.5 Flash Memory Characteristics

Table 21-5. Flash Memory Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
PE _{CYC}	Number of guaranteed program/erase cycles before failure ^a	10,000	100,000	-	cycles
T _{RET}	Data retention at average operating temperature of 85°C	10	-	-	years
T _{PROG}	Word program time	20	-	-	μs
T _{ERASE}	Page erase time	20	-	-	ms
T _{ME}	Mass erase time	200	-	-	ms

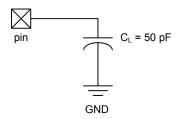

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

21.2 AC Characteristics

21.2.1 Load Conditions

Unless otherwise specified, the following conditions are true for all timing measurements. Timing measurements are for 4-mA drive strength.

Figure 21-1. Load Conditions

21.2.2 Clocks

Table 21-6. Phase Locked Loop (PLL) Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
f _{ref_crystal}	Crystal reference ^a	3.579545	-	8.192	MHz
f _{ref_ext}	External clock reference ^a	3.579545	-	8.192	MHz
f _{pll}	PLL frequency ^b	-	400	-	MHz
T _{READY}	PLL lock time	-	-	0.5	ms

a. The exact value is determined by the crystal value programmed into the XTAL field of the Run-Mode Clock Configuration (RCC) register.

Table 21-7. Clock Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
f _{IOSC}	Internal 12 MHz oscillator frequency	8.4	12	15.6	MHz
f _{IOSC30KHZ}	Internal 30 KHz oscillator frequency	21	30	39	KHz
f _{MOSC}	Main oscillator frequency	1	-	8	MHz
t _{MOSC_per}	Main oscillator period	125	-	1000	ns
f _{ref_crystal_bypass}	Crystal reference using the main oscillator (PLL in BYPASS mode)	1	-	8	MHz

I2 ^a	t _{LP}	Clock Low period	36	-	-	system clocks
I3 ^b	t _{SRT}	<code>I2CSCL/I2CSDA</code> rise time (V $_{\rm IL}$ =0.5 V to V $_{\rm IH}$ =2.4 V)	-	-	(see note b)	ns
I4 ^a	t _{DH}	Data hold time	2	-	-	system clocks
I5 ^c	t _{SFT}	<code>I2CSCL/I2CSDA</code> fall time (V $_{IH}$ =2.4 V to V $_{IL}$ =0.5 V)	-	9	10	ns
I6 ^a	t _{HT}	Clock High time	24	-	-	system clocks
I7 ^a	t _{DS}	Data setup time	18	-	-	system clocks
I8 ^a	t _{SCSR}	Start condition setup time (for repeated start condition only)	36	-	-	system clocks
19 ^a	t _{SCS}	Stop condition setup time	24	-	-	system clocks

- a. Values depend on the value programmed into the TPR bit in the I²C Master Timer Period (I2CMTPR) register; a TPR programmed for the maximum I2CSCL frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I²C interface is designed to scale the actual data transition time to move it to the middle of the I2CSCL Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.
- b. Because I2CSCL and I2CSDA are open-drain-type outputs, which the controller can only actively drive Low, the time I2CSCL or I2CSDA takes to reach a high level depends on external signal capacitance and pull-up resistor values.
- c. Specified at a nominal 50 pF load.

A Serial Flash Loader

A.1 Serial Flash Loader

The Stellaris[®] serial flash loader is a preprogrammed flash-resident utility used to download code to the flash memory of a device without the use of a debug interface. The serial flash loader uses a simple packet interface to provide synchronous communication with the device. The flash loader runs off the crystal and does not enable the PLL, so its speed is determined by the crystal used. The two serial interfaces that can be used are the UART0 and SSI0 interfaces. For simplicity, both the data format and communication protocol are identical for both serial interfaces.

A.2 Interfaces

Once communication with the flash loader is established via one of the serial interfaces, that interface is used until the flash loader is reset or new code takes over. For example, once you start communicating using the SSI port, communications with the flash loader via the UART are disabled until the device is reset.

A.2.1 UART

The Universal Asynchronous Receivers/Transmitters (UART) communication uses a fixed serial format of 8 bits of data, no parity, and 1 stop bit. The baud rate used for communication is automatically detected by the flash loader and can be any valid baud rate supported by the host and the device. The auto detection sequence requires that the baud rate should be no more than 1/32 the crystal frequency of the board that is running the serial flash loader. This is actually the same as the hardware limitation for the maximum baud rate for any UART on a Stellaris[®] device which is calculated as follows:

Max Baud Rate = System Clock Frequency / 16

In order to determine the baud rate, the serial flash loader needs to determine the relationship between its own crystal frequency and the baud rate. This is enough information for the flash loader to configure its UART to the same baud rate as the host. This automatic baud-rate detection allows the host to use any valid baud rate that it wants to communicate with the device.

The method used to perform this automatic synchronization relies on the host sending the flash loader two bytes that are both 0x55. This generates a series of pulses to the flash loader that it can use to calculate the ratios needed to program the UART to match the host's baud rate. After the host sends the pattern, it attempts to read back one byte of data from the UART. The flash loader returns the value of 0xCC to indicate successful detection of the baud rate. If this byte is not received after at least twice the time required to transfer the two bytes, the host can resend another pattern of 0x55, 0x55, and wait for the 0xCC byte again until the flash loader acknowledges that it has received a synchronization pattern correctly. For example, the time to wait for data back from the flash loader should be calculated as at least 2*(20(bits/sync)/baud rate (bits/sec)). For a baud rate of 115200, this time is 2*(20/115200) or 0.35 ms.

A.2.2 SSI

The Synchronous Serial Interface (SSI) port also uses a fixed serial format for communications, with the framing defined as Motorola format with SPH set to 1 and SPO set to 1. See "Frame Formats" on page 312 in the SSI chapter for more information on formats for this transfer protocol. Like the UART, this interface has hardware requirements that limit the maximum speed that the SSI clock can run. This allows the SSI clock to be at most 1/12 the crystal frequency of the board running

the flash loader. Since the host device is the master, the SSI on the flash loader device does not need to determine the clock as it is provided directly by the host.

A.3 Packet Handling

All communications, with the exception of the UART auto-baud, are done via defined packets that are acknowledged (ACK) or not acknowledged (NAK) by the devices. The packets use the same format for receiving and sending packets, including the method used to acknowledge successful or unsuccessful reception of a packet.

A.3.1 Packet Format

All packets sent and received from the device use the following byte-packed format.

```
struct
{
  unsigned char ucSize;
  unsigned char ucCheckSum;
  unsigned char Data[];
};
```

ucSize The first byte received holds the total size of the transfer including

the size and checksum bytes.

ucChecksum This holds a simple checksum of the bytes in the data buffer only.

The algorithm is Data[0]+Data[1]+...+ Data[ucSize-3].

Data This is the raw data intended for the device, which is formatted in

some form of command interface. There should be ucSize-2 bytes of data provided in this buffer to or from the device.

A.3.2 Sending Packets

The actual bytes of the packet can be sent individually or all at once; the only limitation is that commands that cause flash memory access should limit the download sizes to prevent losing bytes during flash programming. This limitation is discussed further in the section that describes the serial flash loader command, COMMAND_SEND_DATA (see "COMMAND_SEND_DATA (0x24)" on page 500).

Once the packet has been formatted correctly by the host, it should be sent out over the UART or SSI interface. Then the host should poll the UART or SSI interface for the first non-zero data returned from the device. The first non-zero byte will either be an ACK (0xCC) or a NAK (0x33) byte from the device indicating the packet was received successfully (ACK) or unsuccessfully (NAK). This does not indicate that the actual contents of the command issued in the data portion of the packet were valid, just that the packet was received correctly.

A.3.3 Receiving Packets

The flash loader sends a packet of data in the same format that it receives a packet. The flash loader may transfer leading zero data before the first actual byte of data is sent out. The first non-zero byte is the size of the packet followed by a checksum byte, and finally followed by the data itself. There is no break in the data after the first non-zero byte is sent from the flash loader. Once the device communicating with the flash loader receives all the bytes, it must either ACK or NAK the packet to indicate that the transmission was successful. The appropriate response after sending a NAK to the flash loader is to resend the command that failed and request the data again. If needed, the host may send leading zeros before sending down the ACK/NAK signal to the flash loader, as the

flash loader only accepts the first non-zero data as a valid response. This zero padding is needed by the SSI interface in order to receive data to or from the flash loader.

A.4 Commands

The next section defines the list of commands that can be sent to the flash loader. The first byte of the data should always be one of the defined commands, followed by data or parameters as determined by the command that is sent.

A.4.1 COMMAND_PING (0X20)

This command simply accepts the command and sets the global status to success. The format of the packet is as follows:

```
Byte[0] = 0x03;
Byte[1] = checksum(Byte[2]);
Byte[2] = COMMAND_PING;
```

The ping command has 3 bytes and the value for COMMAND_PING is 0x20 and the checksum of one byte is that same byte, making Byte[1] also 0x20. Since the ping command has no real return status, the receipt of an ACK can be interpreted as a successful ping to the flash loader.

A.4.2 COMMAND_GET_STATUS (0x23)

This command returns the status of the last command that was issued. Typically, this command should be sent after every command to ensure that the previous command was successful or to properly respond to a failure. The command requires one byte in the data of the packet and should be followed by reading a packet with one byte of data that contains a status code. The last step is to ACK or NAK the received data so the flash loader knows that the data has been read.

```
Byte[0] = 0x03
Byte[1] = checksum(Byte[2])
Byte[2] = COMMAND_GET_STATUS
```

A.4.3 COMMAND_DOWNLOAD (0x21)

This command is sent to the flash loader to indicate where to store data and how many bytes will be sent by the COMMAND_SEND_DATA commands that follow. The command consists of two 32-bit values that are both transferred MSB first. The first 32-bit value is the address to start programming data into, while the second is the 32-bit size of the data that will be sent. This command also triggers an erase of the full area to be programmed so this command takes longer than other commands. This results in a longer time to receive the ACK/NAK back from the board. This command should be followed by a COMMAND_GET_STATUS to ensure that the Program Address and Program size are valid for the device running the flash loader.

The format of the packet to send this command is a follows:

```
Byte[0] = 11
Byte[1] = checksum(Bytes[2:10])
Byte[2] = COMMAND_DOWNLOAD
Byte[3] = Program Address [31:24]
Byte[4] = Program Address [23:16]
Byte[5] = Program Address [15:8]
Byte[6] = Program Address [7:0]
Byte[7] = Program Size [31:24]
```

```
Byte[8] = Program Size [23:16]
Byte[9] = Program Size [15:8]
Byte[10] = Program Size [7:0]
```

A.4.4 COMMAND_SEND_DATA (0x24)

This command should only follow a COMMAND_DOWNLOAD command or another COMMAND_SEND_DATA command if more data is needed. Consecutive send data commands automatically increment address and continue programming from the previous location. The caller should limit transfers of data to a maximum 8 bytes of packet data to allow the flash to program successfully and not overflow input buffers of the serial interfaces. The command terminates programming once the number of bytes indicated by the COMMAND_DOWNLOAD command has been received. Each time this function is called it should be followed by a COMMAND_GET_STATUS to ensure that the data was successfully programmed into the flash. If the flash loader sends a NAK to this command, the flash loader does not increment the current address to allow retransmission of the previous data.

```
Byte[0] = 11
Byte[1] = checksum(Bytes[2:10])
Byte[2] = COMMAND_SEND_DATA
Byte[3] = Data[0]
Byte[4] = Data[1]
Byte[5] = Data[2]
Byte[6] = Data[3]
Byte[7] = Data[4]
Byte[8] = Data[5]
Byte[9] = Data[6]
Byte[10] = Data[7]
```

A.4.5 COMMAND_RUN (0x22)

This command is used to tell the flash loader to execute from the address passed as the parameter in this command. This command consists of a single 32-bit value that is interpreted as the address to execute. The 32-bit value is transmitted MSB first and the flash loader responds with an ACK signal back to the host device before actually executing the code at the given address. This allows the host to know that the command was received successfully and the code is now running.

```
Byte[0] = 7
Byte[1] = checksum(Bytes[2:6])
Byte[2] = COMMAND_RUN
Byte[3] = Execute Address[31:24]
Byte[4] = Execute Address[23:16]
Byte[5] = Execute Address[15:8]
Byte[6] = Execute Address[7:0]
```

A.4.6 COMMAND_RESET (0x25)

This command is used to tell the flash loader device to reset. This is useful when downloading a new image that overwrote the flash loader and wants to start from a full reset. Unlike the COMMAND_RUN command, this allows the initial stack pointer to be read by the hardware and set up for the new code. It can also be used to reset the flash loader if a critical error occurs and the host device wants to restart communication with the flash loader.

```
Byte[0] = 3
Byte[1] = checksum(Byte[2])
Byte[2] = COMMAND_RESET
```

The flash loader responds with an ACK signal back to the host device before actually executing the software reset to the device running the flash loader. This allows the host to know that the command was received successfully and the part will be reset.

C Ordering and Contact Information

C.1 Ordering Information

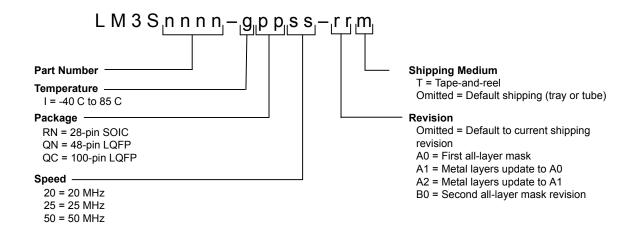

Table C-1. Part Ordering Information

Orderable Part Number	Description
LM3S2432-IQC50	Stellaris® LM3S2432 Microcontroller
LM3S2432-IQC50(T)	Stellaris [®] LM3S2432 Microcontroller

C.2 Kits

The Luminary Micro Stellaris[®] Family provides the hardware and software tools that engineers need to begin development quickly.

- Reference Design Kits accelerate product development by providing ready-to-run hardware, and comprehensive documentation including hardware design files:
 - http://www.luminarymicro.com/products/reference_design_kits/
- Evaluation Kits provide a low-cost and effective means of evaluating Stellaris® microcontrollers before purchase:
 - http://www.luminarymicro.com/products/evaluation kits/
- Development Kits provide you with all the tools you need to develop and prototype embedded applications right out of the box:
 - http://www.luminarymicro.com/products/boards.html

See the Luminary Micro website for the latest tools available or ask your Luminary Micro distributor.

C.3 Company Information

Luminary Micro, Inc. designs, markets, and sells ARM Cortex-M3-based microcontrollers (MCUs). Austin, Texas-based Luminary Micro is the lead partner for the Cortex-M3 processor, delivering the world's first silicon implementation of the Cortex-M3 processor. Luminary Micro's introduction of the

Stellaris® family of products provides 32-bit performance for the same price as current 8- and 16-bit microcontroller designs. With entry-level pricing at \$1.00 for an ARM technology-based MCU, Luminary Micro's Stellaris product line allows for standardization that eliminates future architectural upgrades or software tool changes.

Luminary Micro, Inc. 108 Wild Basin, Suite 350 Austin, TX 78746 Main: +1-512-279-8800 Fax: +1-512-279-8879 http://www.luminarymicro.com sales@luminarymicro.com

C.4 Support Information

For support on Luminary Micro products, contact: support@luminarymicro.com +1-512-279-8800, ext. 3
